Data Modeling (1/2)

- A technique aimed at optimizing the way that information is stored and used within an organization
 - Begins with the **identification of the main data groups**, continues by **defining the detailed content** of each of these groups.
 - Result: **structured definitions** for all of the information that is stored and used within a given system.
- An **essential precursor** to analysis, design, maintenance & documentation and improving the performance of an existing system.

Data Modeling (2/2)

There are three different types of data models produced while progressing from requirements to the actual database.

- Conceptual data model: a set of technology independent specifications about the data and is used to discuss initial requirements with the business stakeholders.
- Logical data model: the structures of the data that can be implemented in databases.
- Physical data model: that organizes the data into tables, and accounts for access, performance and storage details.

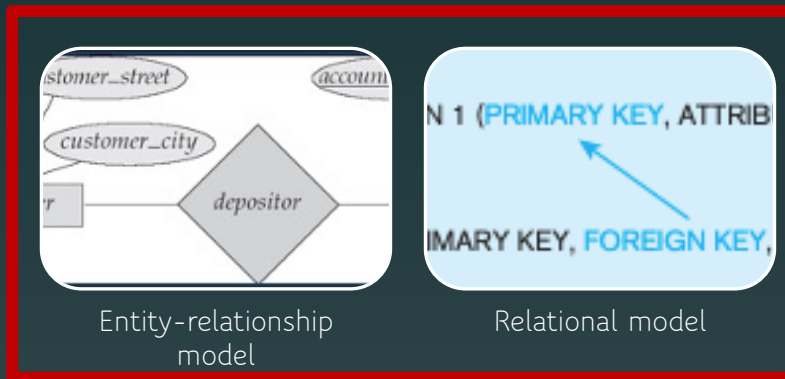

Data Model (1/2)

A collection of tools for describing:

Data Model (2/2)

Types of data model:

Older data models

Entity Relationship Model

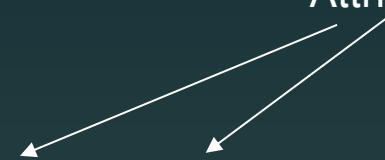

- Widely used for database design
 - Database design in E-R model usually converted into design in Relational Model
- Models an enterprise as a collection of *entities* and *relationships*
 - **Entity**: a “thing” or “object” in the enterprise that is distinguishable from other objects
 - **Relationship**: an association among several entities
- Represented diagrammatically by an *entity-relationship diagram* (ERD)

Relational Model

- Consist of collection of tables to represent data and the relationship among those data
- Example of tabular data in the relational model

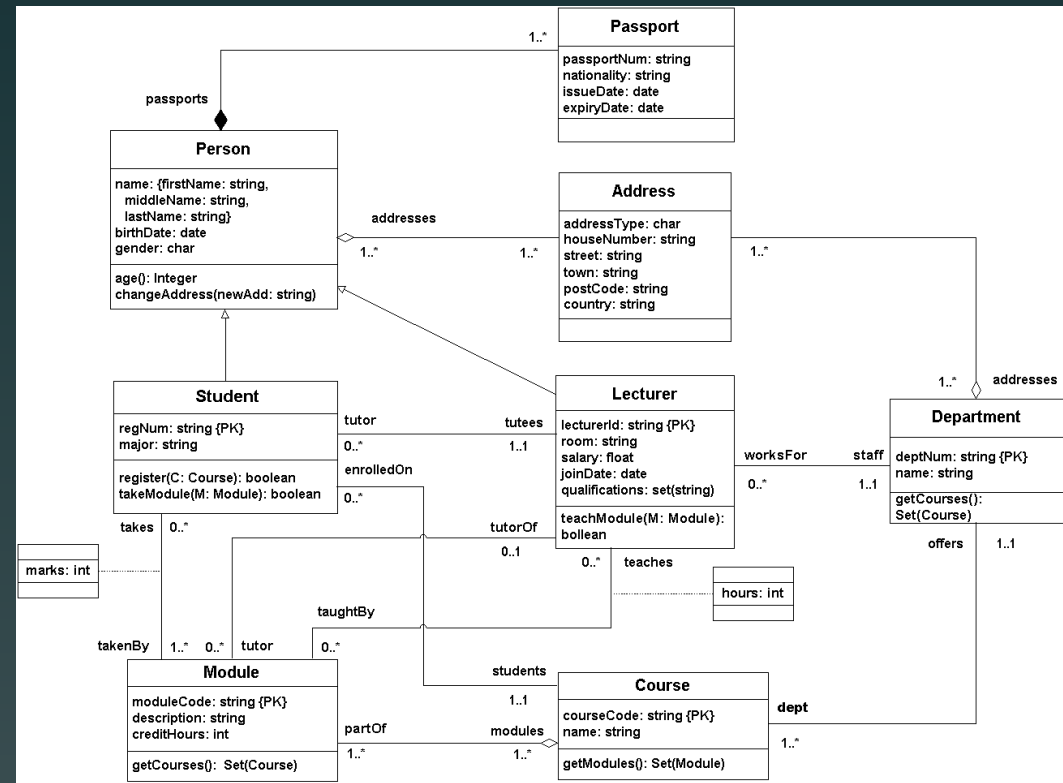

Attributes

<i>customer_id</i>	<i>customer_name</i>	<i>customer_street</i>	<i>customer_city</i>	<i>account_number</i>
192-83-7465	Johnson	12 Alma St.	Palo Alto	A-101
192-83-7465	Johnson	12 Alma St.	Palo Alto	A-201
677-89-9011	Hayes	3 Main St.	Harrison	A-102
182-73-6091	Turner	123 Putnam St.	Stamford	A-305
321-12-3123	Jones	100 Main St.	Harrison	A-217
336-66-9999	Lindsay	175 Park Ave.	Pittsfield	A-222
019-28-3746	Smith	72 North St.	Rye	A-201

Object-Oriented Data Model

- Adaptation of the object-oriented programming paradigm (e.g. Smalltalk, C++) to database systems
- The *object-oriented paradigm* is based on *encapsulating* code and data related to an object into single unit

Object Structure

```
class Person {  
    /* variable */  
    Name      name;  
    date      birthDate;  
    string     address;  
    char       gender;  
    /* messages */  
    int        age();  
    int        changeAddress(string newAdd);  
    Name       getName();  
    date       getBirthDate();  
    string     getAddress();  
    char       getGender();  
  
};  
  
string get-address() {  
    return address;  
}
```

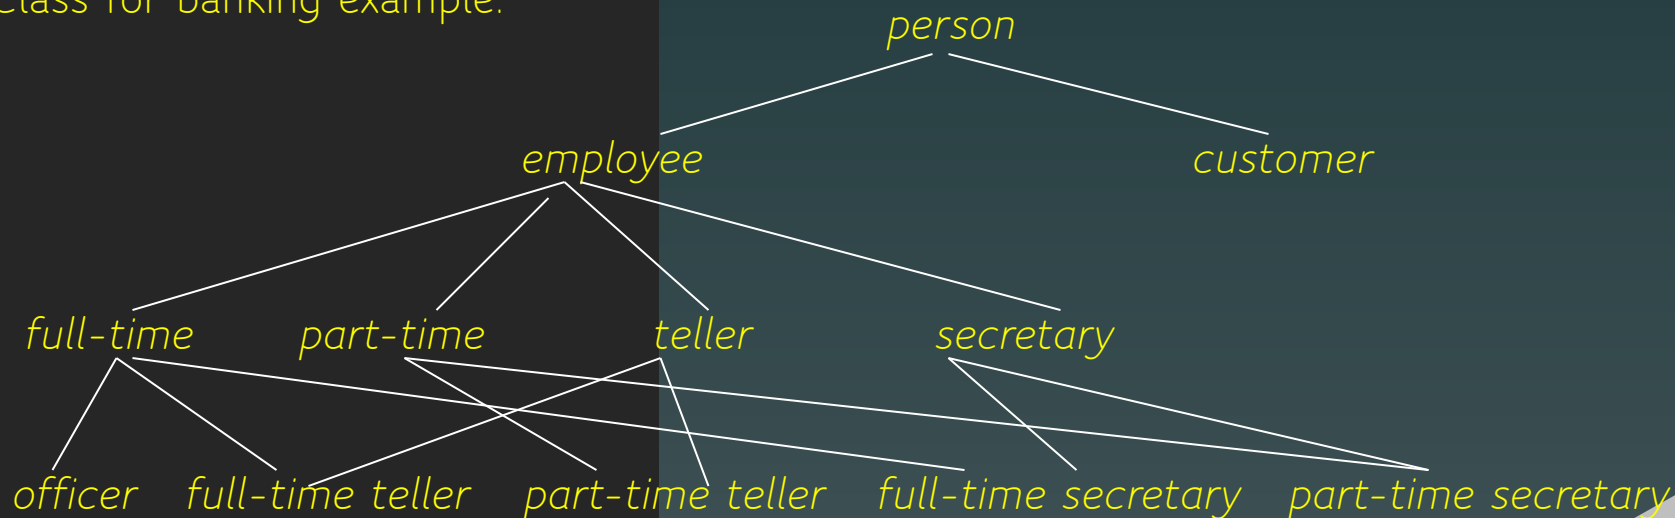

An object has associated with it:

- A **set of variables** that contain the data for the object. The value of each variable is itself an object.
- A **set of messages** to which the object responds; each message may have zero, one, or more *parameters*.
- A **set of methods**, each of which is a body of code to implement a message; a method returns a value as the *response* to the message

Object- Relational Data Model

- Extend the relational data model by including object orientation and a richer type system including collection types
 - Object orientation provides inheritance with subtypes and sub tables
 - Collection types include nested relations, sets, multisets, and arrays
- Preserve relational foundations, in particular the declarative access to data, while extending modeling power

Class for banking example:

Semi Structured Data Model (ex: XML)

- The ability to specify new tags, and to create nested tag structures made XML a great way to exchange **data**, not just documents
- XML has become the basis for all new generation data interchange formats.
- A wide variety of tools is available for parsing, browsing and querying XML documents/data

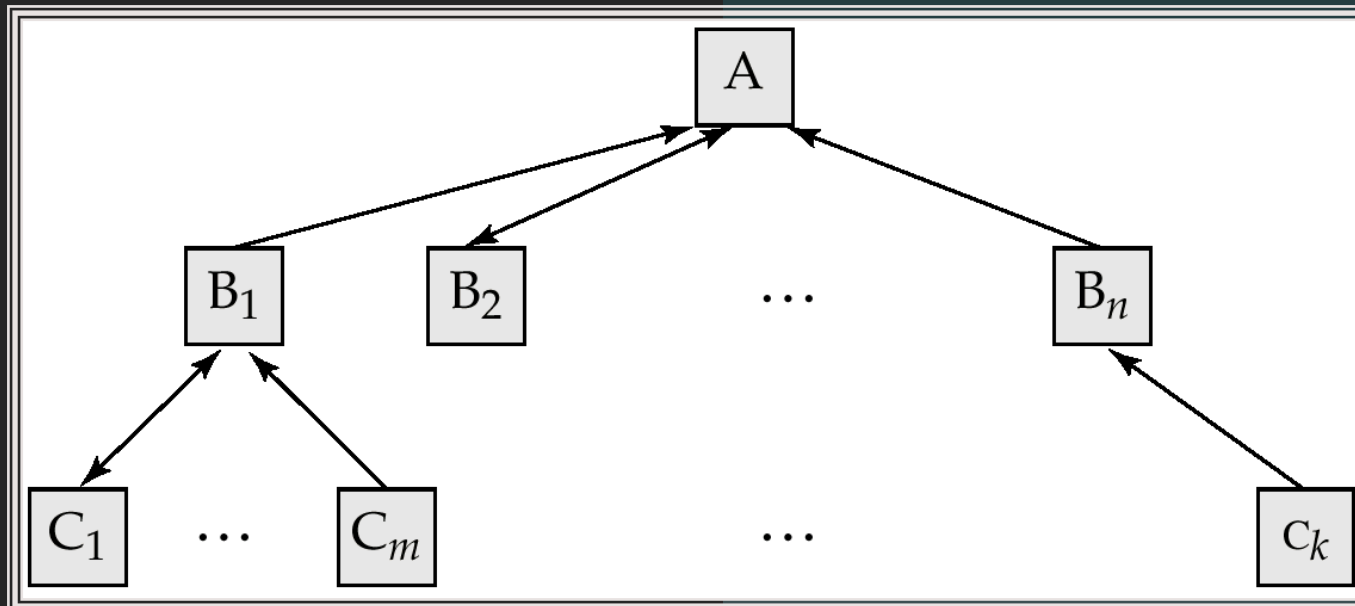

- Characteristics:
 - organized in semantic entities
 - similar entities are grouped together
 - entities in same group may not have same attributes
 - order of attributes not necessarily important
 - not all attributes may be required
 - size of same attributes in a group may differ
 - type of same attributes in a group may differ

→ Self-describing, irregular data, no a priori structure

```
<bank>
  <account>
    <account-number>A-101</account-number>
    <branch-name>Downtown</branch-name>
    <balance>500</balance>
  </account>
  ...
  <customer>
    <customer-name>Johnson</customer-name>
    <customer-street>Alma</customer-street>
    <customer-city>Palo Alto</customer-city>
  </customer>
  ...
</bank>
```

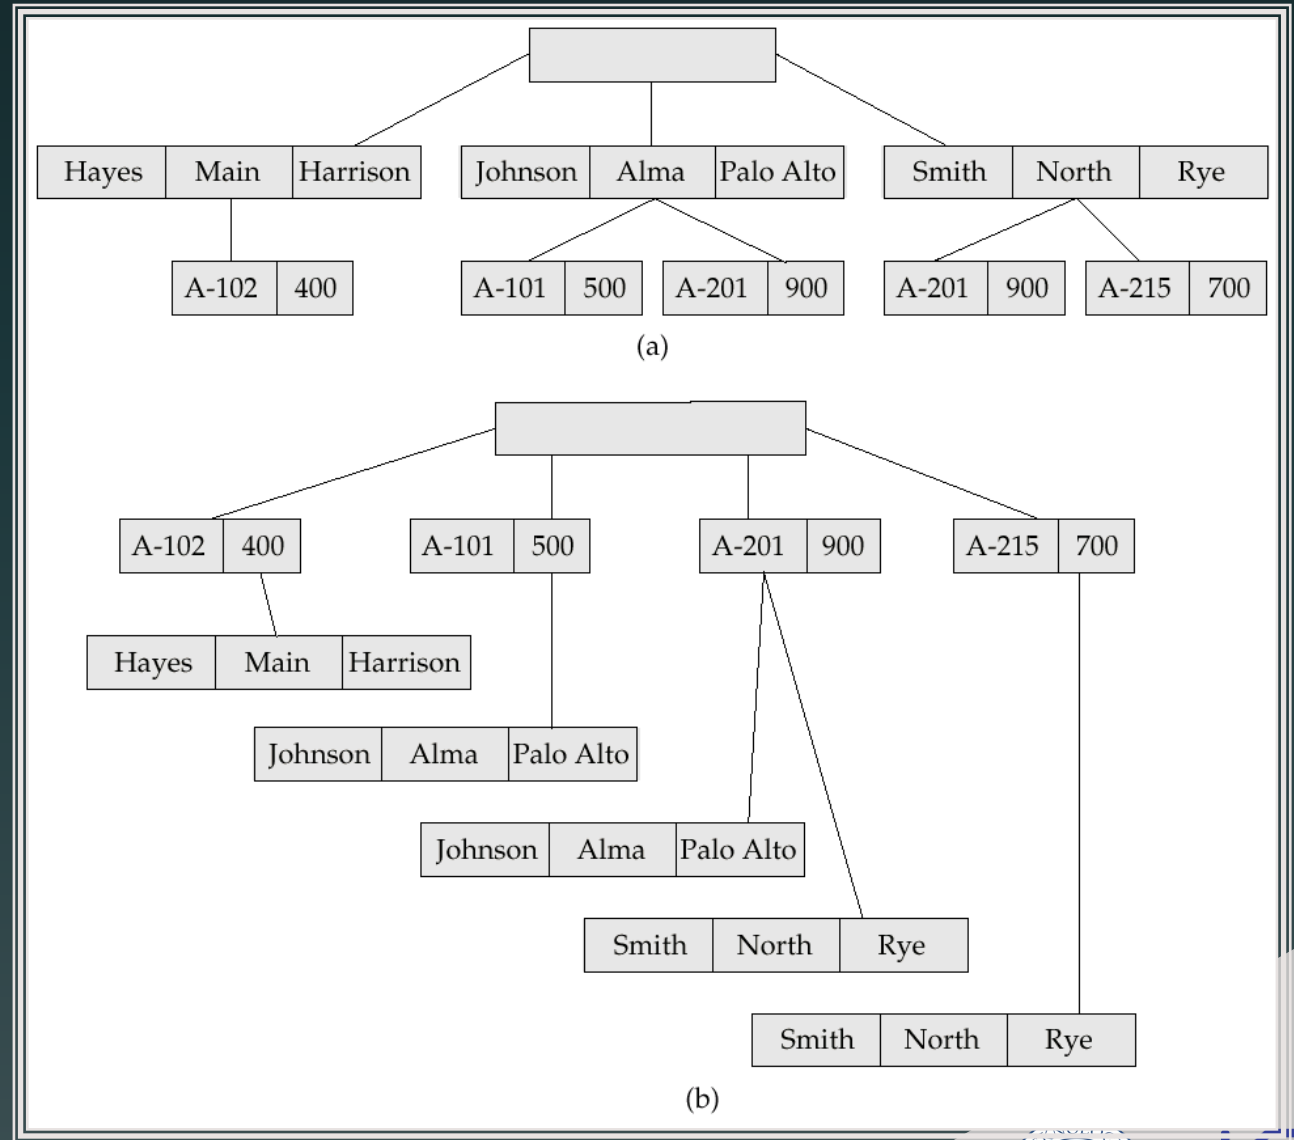

Hierarchical Model (1/2)

- World's leading mainframe hierarchical database system in the 1970s and early 1980s
- Database schema is represented as a collection of tree-structure diagrams
 - *Single* instance of a database tree
 - The root of this tree is a dummy node
 - The children of that node are actual instances of the appropriate record type
- The schema for a hierarchical database consists of
 - *boxes*, which correspond to record types
 - *lines*, which correspond to links
- Record types are organized in the form of a *rooted tree*

A parent *may* have an arrow pointing to a child, but a child *must* have an arrow pointing to its parent

Hierarchical Model (2/2)

Network Model (1/2)

- Data are represented by collections of *records*.
 - similar to an entity in the E-R model
 - Records and their fields are represented as *record type*
- Relationships among data are represented by *links*
 - similar to a restricted (binary) form of an E-R relationship
 - restrictions on links depend on whether the relationship is many-many, many-to-one, or one-to-one.

```
type customer = record  
    customer-name: string;  
    customer-street: string;  
    customer-city: string;  
end;
```

```
type account = record  
    account-number: integer;  
    balance: integer;  
end;
```

Network Model (2/2)

- Graph like structure
 - Child may have multiple parent
- A data-structure diagram consists of two basic components:
 - **Boxes**, which correspond to record types
 - **Lines**, which correspond to links
- Specifies the overall logical structure of the database
