The background of the slide features a complex, abstract network graph. It consists of numerous small, semi-transparent nodes represented by small circles with a central dot, and a dense web of thin, curved lines in various colors (red, blue, green, yellow) connecting them. Some nodes are highlighted with larger circles and thicker lines. The overall effect is one of data flow or connectivity.

Definition of Terms

Definition (1/3)

Database	organized collection of logically related data
Data	stored representations of meaningful objects and events Structured: numbers, text, dates Unstructured: images, video, documents

Example:	Baker, Kenneth D.	324917628
	Doyle, Joan E.	476193248
	Finkle, Clive R.	548429344
	Lewis, John C.	551742186
	McFerran, Debra R.	409723145

KNOWLEDGE & SOFTWARE ENGINEERING

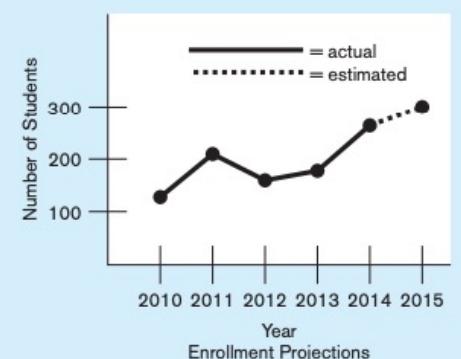

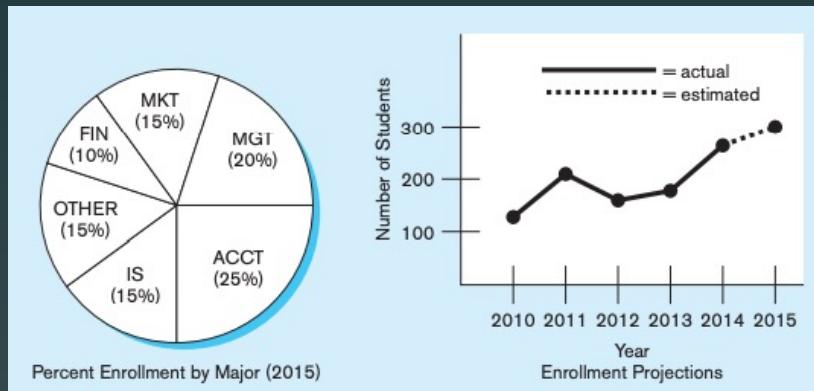

Definition (2/3)

Information

data processed to increase knowledge in the person using the data

Example:

Class Roster			
Course:	MGT 500 Business Policy	Semester:	Spring 2015
Section:	2		
Name	ID	Major	GPA
Baker, Kenneth D.	324917628	MGT	2.9
Doyle, Joan E.	476193248	MKT	3.4
Finkle, Clive R.	548429344	PRM	2.8
Lewis, John C.	551742186	MGT	3.7
McFerran, Debra R.	409723145	IS	2.9
Sisneros, Michael	392416582	ACCT	3.3

Summarized data -
Graphical displays turn
data into useful
information that
managers can use for
decision making and
interpretation

Data in context - Context helps users understand data

KNOWLEDGE & SOFTWARE ENGINEERING

Definition (3/3)

Metadata data that describes the properties and context of user data

Example:

TABLE 1-1 Example Metadata for Class Roster

Data Item		Metadata				
Name	Type	Length	Min	Max	Description	Source
Course	Alphanumeric	30			Course ID and name	Academic Unit
Section	Integer	1	1	9	Section number	Registrar
Semester	Alphanumeric	10			Semester and year	Registrar
Name	Alphanumeric	30			Student name	Student IS
ID	Integer	9			Student ID (SSN)	Student IS
Major	Alphanumeric	4			Student major	Student IS
GPA	Decimal	3	0.0	4.0	Student grade point average	Academic Unit

Descriptions of the properties or characteristics of the data, including data types, field sizes, allowable values, and data context

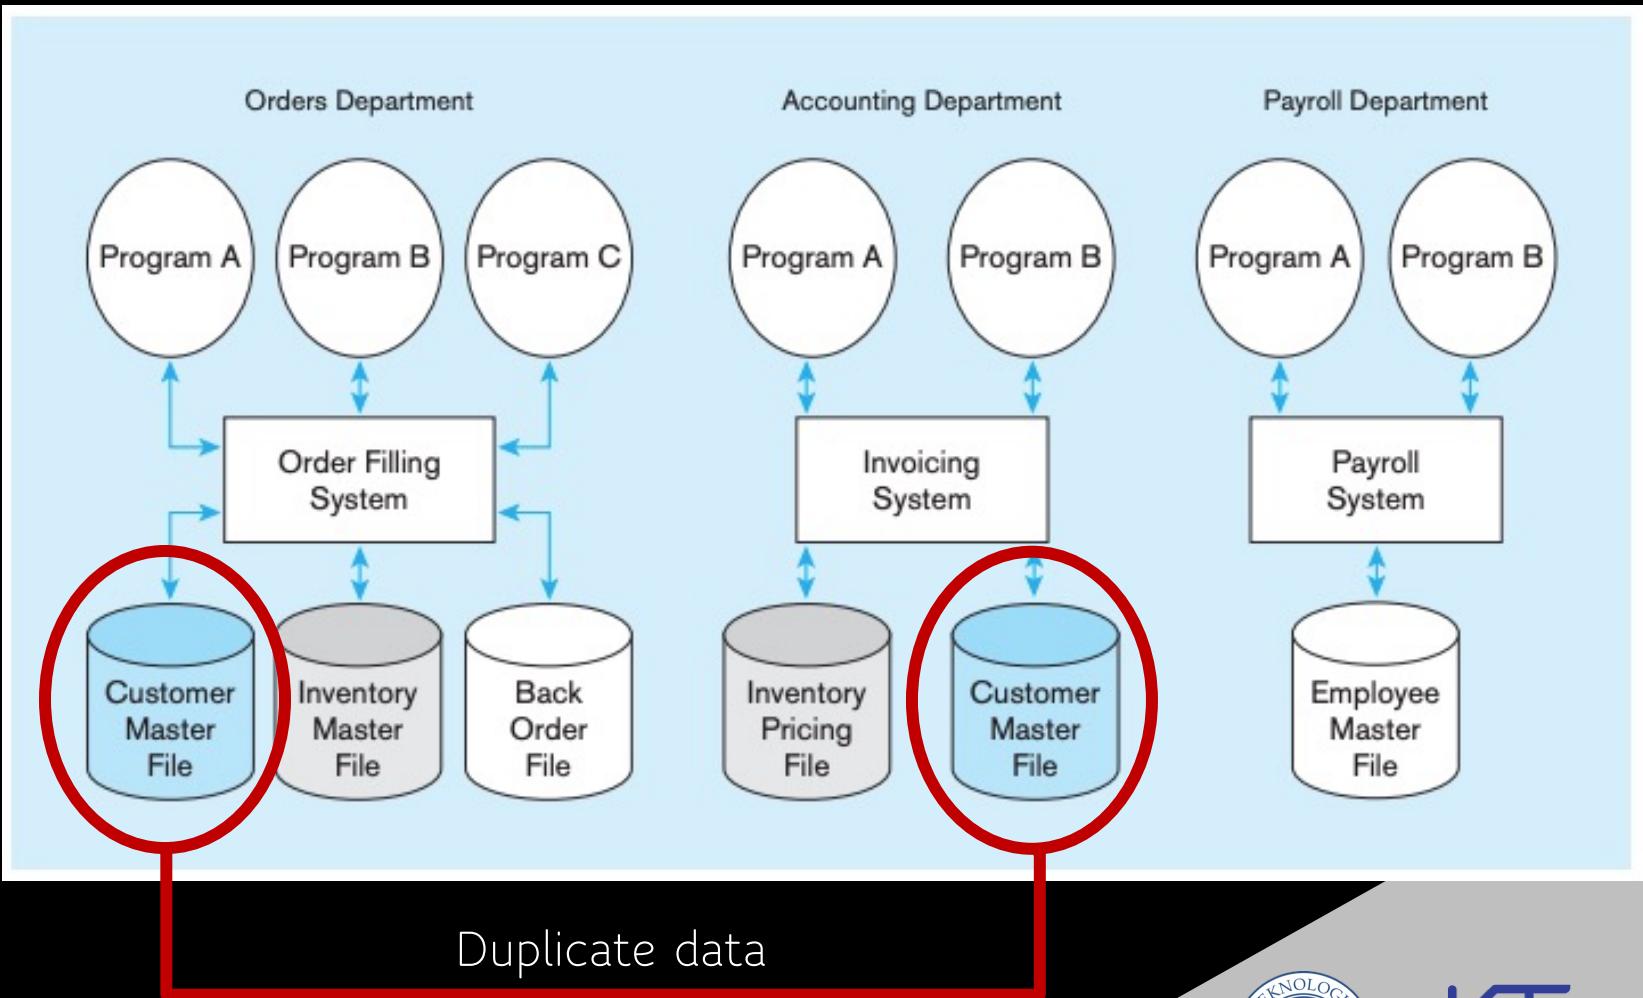

File Processing System vs The Database Approach

Traditional File Processing System

When computer-based data processing was first available, there were no databases. To be useful for business applications, computers had to store, manipulate, and retrieve large files of data.

File processing systems at Pine Valley Furniture Company

Disadvantages of File Processing (1)

Program-Data Dependence	Data Redundancy (Duplication of data)	Limited Data Sharing	Lengthy Development Times	Excessive Program Maintenance
<ul style="list-style-type: none">All programs maintain metadata for each file they use	<ul style="list-style-type: none">Different systems/programs have separate copies of the same data	<ul style="list-style-type: none">No centralized control of data	<ul style="list-style-type: none">Programmers must design their own file formats	<ul style="list-style-type: none">80% of information systems budget

Disadvantages of File Processing (2)

Difficulty in accessing data	Data isolation	Integrity problems	Atomicity of updates	Concurrent access by multiple users	Security problems
<ul style="list-style-type: none">Need to write a new program to carry out each new task	<ul style="list-style-type: none">Multiple files and formats	<ul style="list-style-type: none">Integrity constraints (e.g., account balance > 0) become “buried” in program code rather than being stated explicitlyHard to add new constraints or change existing ones	<ul style="list-style-type: none">Failures may leave database in an inconsistent state with partial updates carried out	<ul style="list-style-type: none">Concurrent access needed for performanceUncontrolled concurrent accesses can lead to inconsistencies	<ul style="list-style-type: none">Hard to provide user access to some, but not all, data

Problems with Data Dependency

Each application programmer must maintain their own data

Each application program needs to include code for the metadata of each file

Each application program must have its own processing routines for reading, inserting, updating and deleting data

Lack of coordination and central control

Non-standard file formats

Problems with Data Redundancy

Waste of space to have duplicate data

Causes more maintenance headaches

The biggest Problem:

- When data changes in one file, could cause inconsistencies
- Compromises *data integrity*

Solution : The Database Approach

CENTRAL REPOSITORY OF
SHARED DATA

DATA IS MANAGED BY A
CONTROLLING AGENT

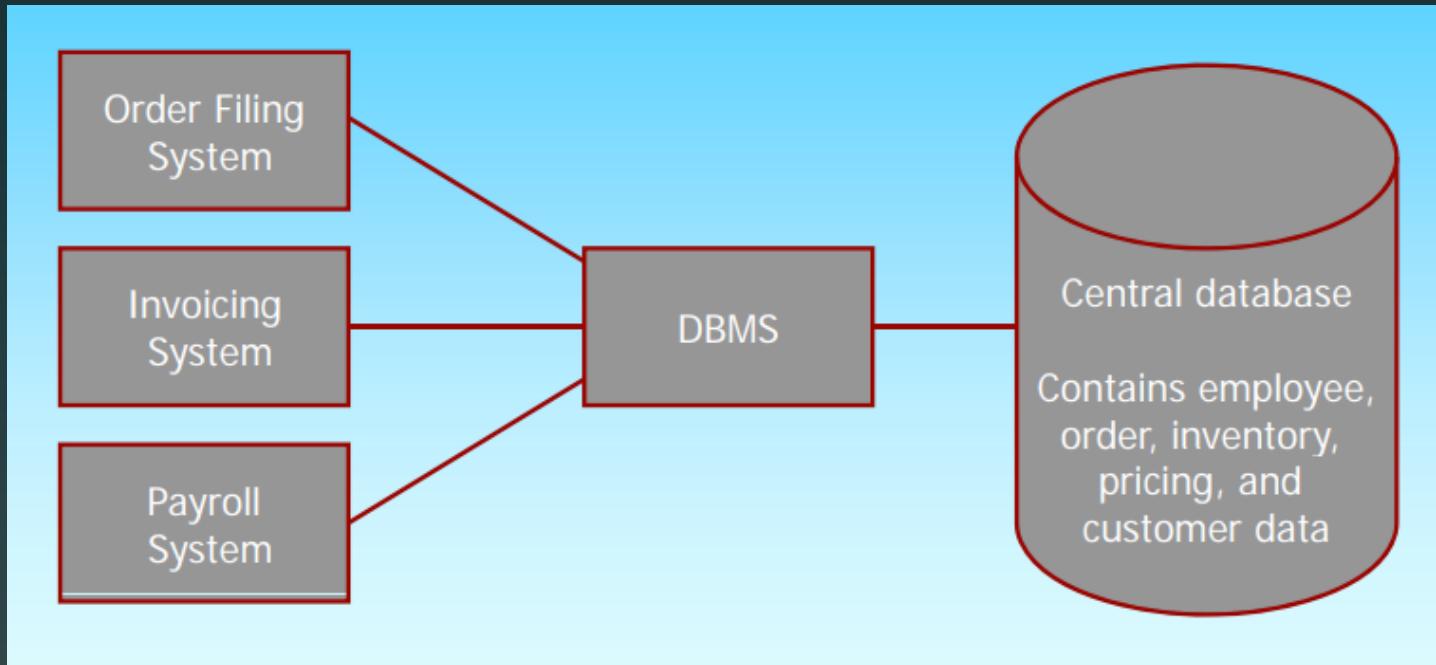

STORED IN A STANDARDIZED,
CONVENIENT FORM

Requires a Database Management System (DBMS)

Database Management System (DBMS)

A software system that is used to create, maintain, and provide controlled access to user databases

DBMS manages data resources like an operating system manages hardware resources

Advantages of Database Approach

Improved Data Sharing	Enforcement of Standards	Improved Data Quality	Better Data Accessibility/Responsiveness	Security, Backup/Recovery, Concurrency
<ul style="list-style-type: none">Different users get different views of the data	<ul style="list-style-type: none">All data access is done in the same way	<ul style="list-style-type: none">Constraints, data validation rules	<ul style="list-style-type: none">Use of standard data query language (SQL)	<ul style="list-style-type: none">Disaster recovery is easier

Costs and Risks of the Database Approach

Up-front costs

- Installation Management Cost and Complexity
- Conversion Costs

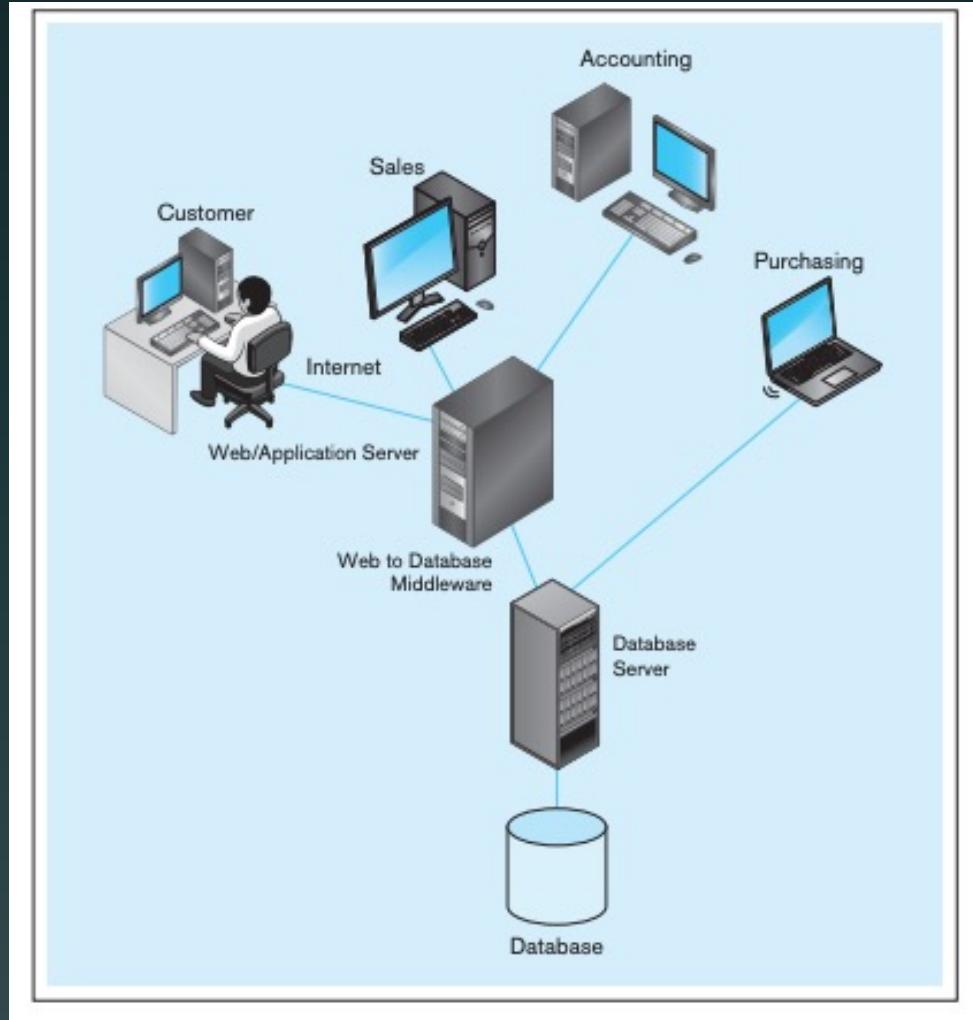

Ongoing Costs

- Requires New, Specialized Personnel
- Need for Explicit Backup and Recovery

Organizational Conflict

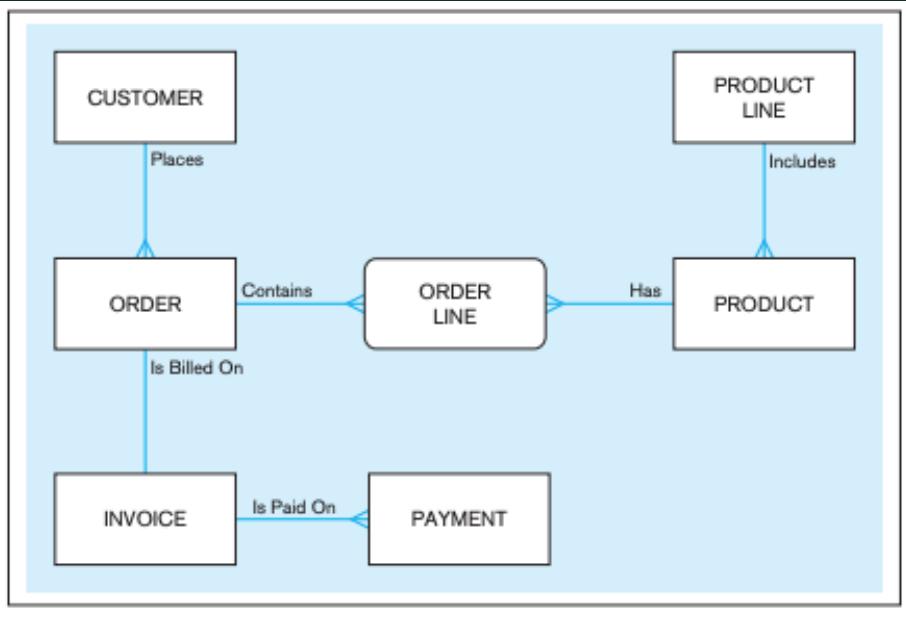

- Old habits die hard

Developing a database application for Pine Valley Furniture Company (1/4)

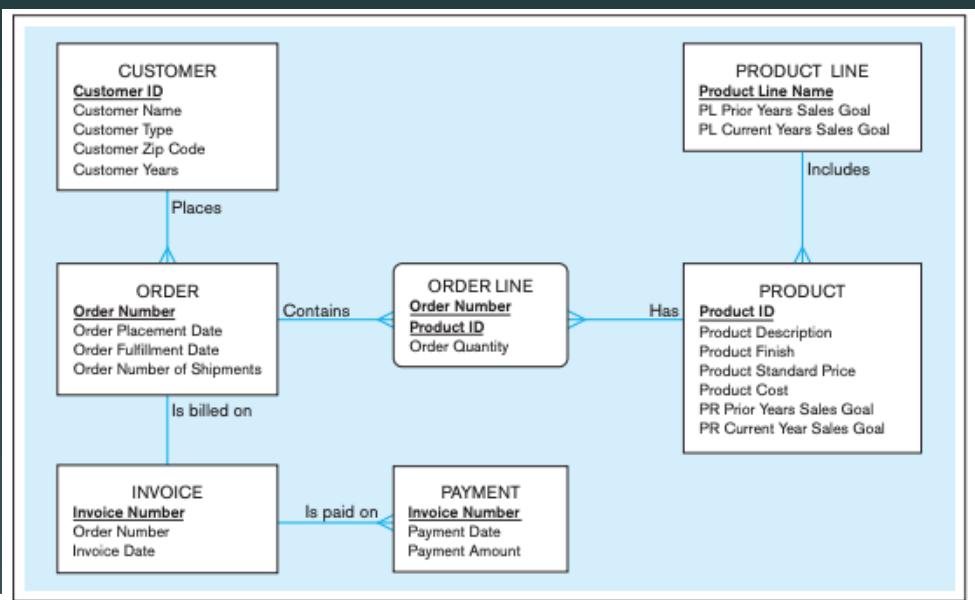

Computer System for Pine Valley Furniture Company

Preliminary data model for Home Office product line marketing support system

Project data model for Home Office product line marketing support system

Developing a database application for Pine Valley Furniture Company (3/4)

Four relations (Pine Valley Furniture Company)

(a) Order and Order Line Tables

The image shows four Microsoft Access tables side-by-side:

- Order_T**: Contains 10 records of orders with IDs 1001 to 1010, dates from 10/21/2015 to 11/5/2015, and customer ID 1.
- OrderLine_T**: Contains 20 records of order lines for various products, with IDs 1001 to 1010 and quantities ranging from 1 to 10.
- Customer_T**: Contains 15 records of customer names, numbered 1 to 15.
- Product_T**: Contains 8 records of product descriptions and types, numbered 1 to 8.

(b) Customer table

CustomerID	CustomerName
1	Contemporary Casuals
2	Value Furniture
3	Home Furnishings
4	Eastern Furniture
5	Impressions
6	Furniture Gallery
7	Period Furniture
8	California Classics
9	M and H Casual Furniture
10	Seminole Interiors
11	American Euro Lifestyles
12	Battle Creek Furniture
13	Heritage Furnishings
14	Kaneohe Homes
15	Mountain Scenes

(c) Product table

ProductID	ProductDescription	ProductType
1	End Table	Cherry
2	Coffee Table	Natural
3	Computer Desk	Natural
4	Entertainment Center	Natural
5	Writers Desk	Cherry
6	8-Drawer Desk	White
7	Dining Table	Natural
8	Computer Desk	Walnut

Developing a database application for Pine Valley Furniture Company (4/4)

```
SELECT Product.ProductID, Product.ProductDescription, Product.PRCurrentYearSalesGoal,  
       (OrderQuantity * ProductPrice) AS SalesToDate  
FROM Order.OrderLine, Product.ProductLine  
WHERE Order.OrderNumber = OrderLine.OrderNumber  
AND Product.ProductID = OrderedProduct.ProductID  
AND Product.ProductID = ProductLine.ProductID  
AND Product.ProductLineName = "Home Office";
```

Home Office Sales to Date : Select Query				
	Product ID	Product Description	PR Current Year Sales Goal	Sales to Date
	3	Computer Desk	\$23,500.00	5625
	10	96" Bookcase	\$22,500.00	4400
	5	Writer's Desk	\$26,500.00	650
	3	Computer Desk	\$23,500.00	3750
	7	48" Bookcase	\$17,000.00	2250
	5	Writer's Desk	\$26,500.00	3800

Customer invoice (Pine Valley Furniture Company)

PVFC Customer Invoice

Customer ID: 2 Order Number: 1006
Customer Name: Value Furniture Order Date: 10/24/2000

Address: 15145 S.W. 17th St.
Plano, TX 75094

Product_ID	Product Description	Finish	Quantity	Unit Price	Extended Price:
7	Dining Table	Natural As	2	\$800.00	\$1,600.00
5	Writer's Desk	Cherry	2	\$325.00	\$650.00
4	Entertainment Center	Natural M	1	\$650.00	\$650.00
Total					\$2,900.00

SQL query for Home Office sales-to-goal comparison

Home Office product line sales comparison

Database Applications

KNOWLEDGE & SOFTWARE ENGINEERING

Components of the Database Environment

CASE Tools – computer-aided software engineering

Repository – centralized storehouse of metadata

Database Management System (DBMS) – software for managing the database

Database – storehouse of the data

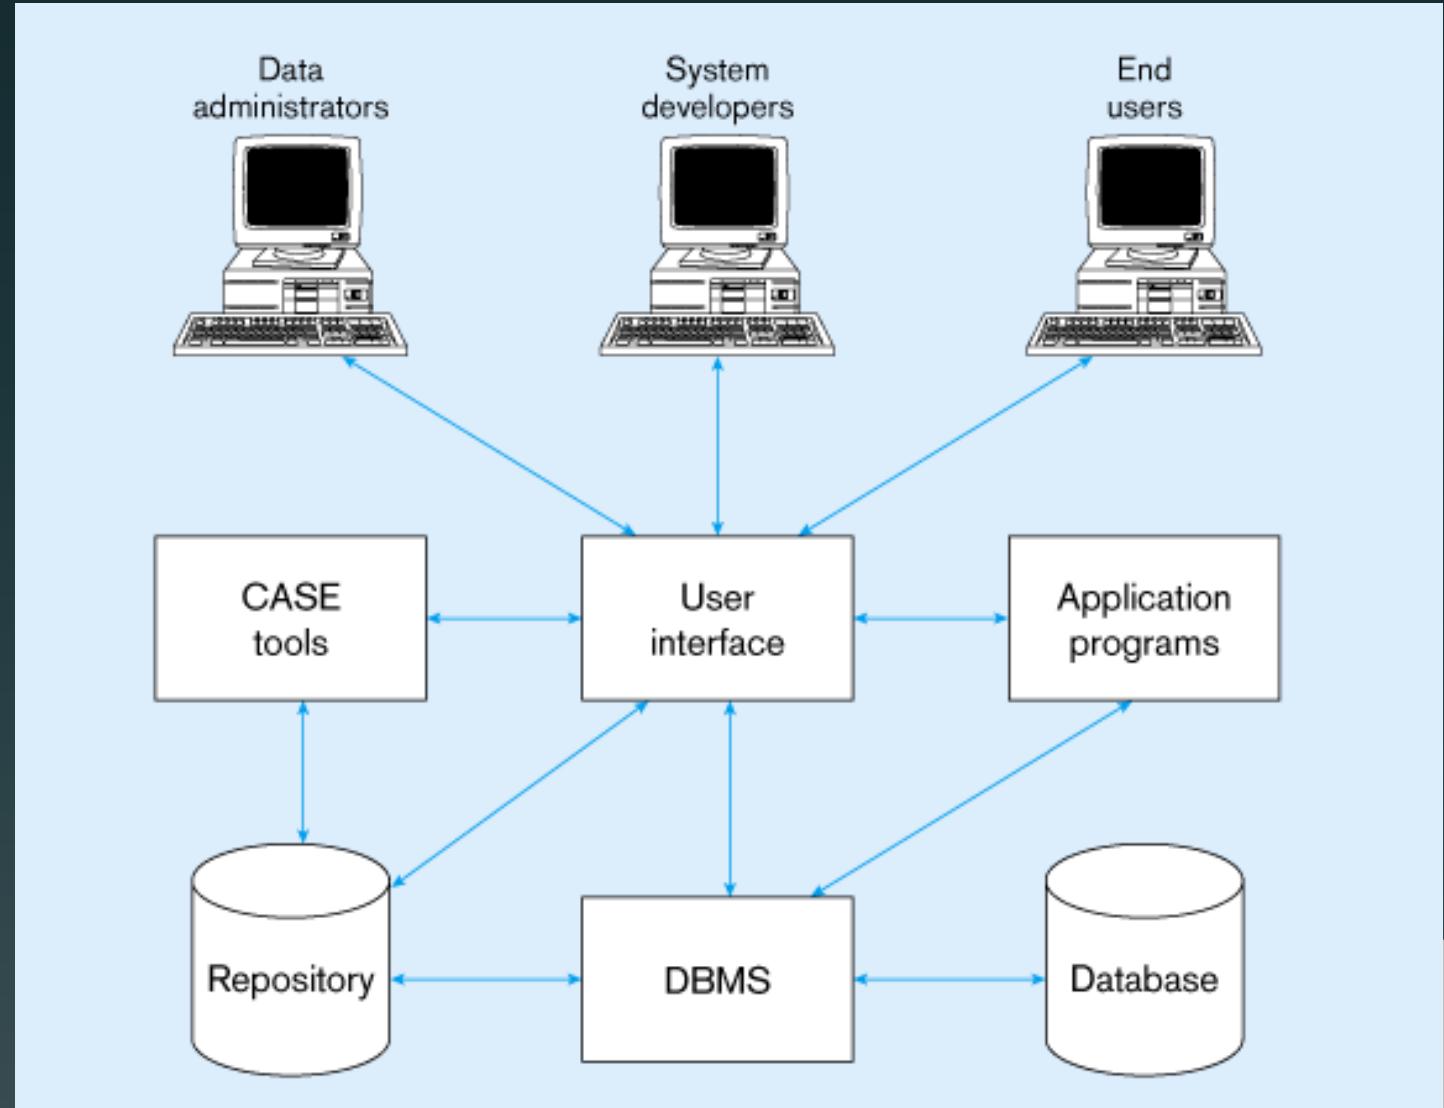

Application Programs – software using the data

User Interface – text and graphical displays to users

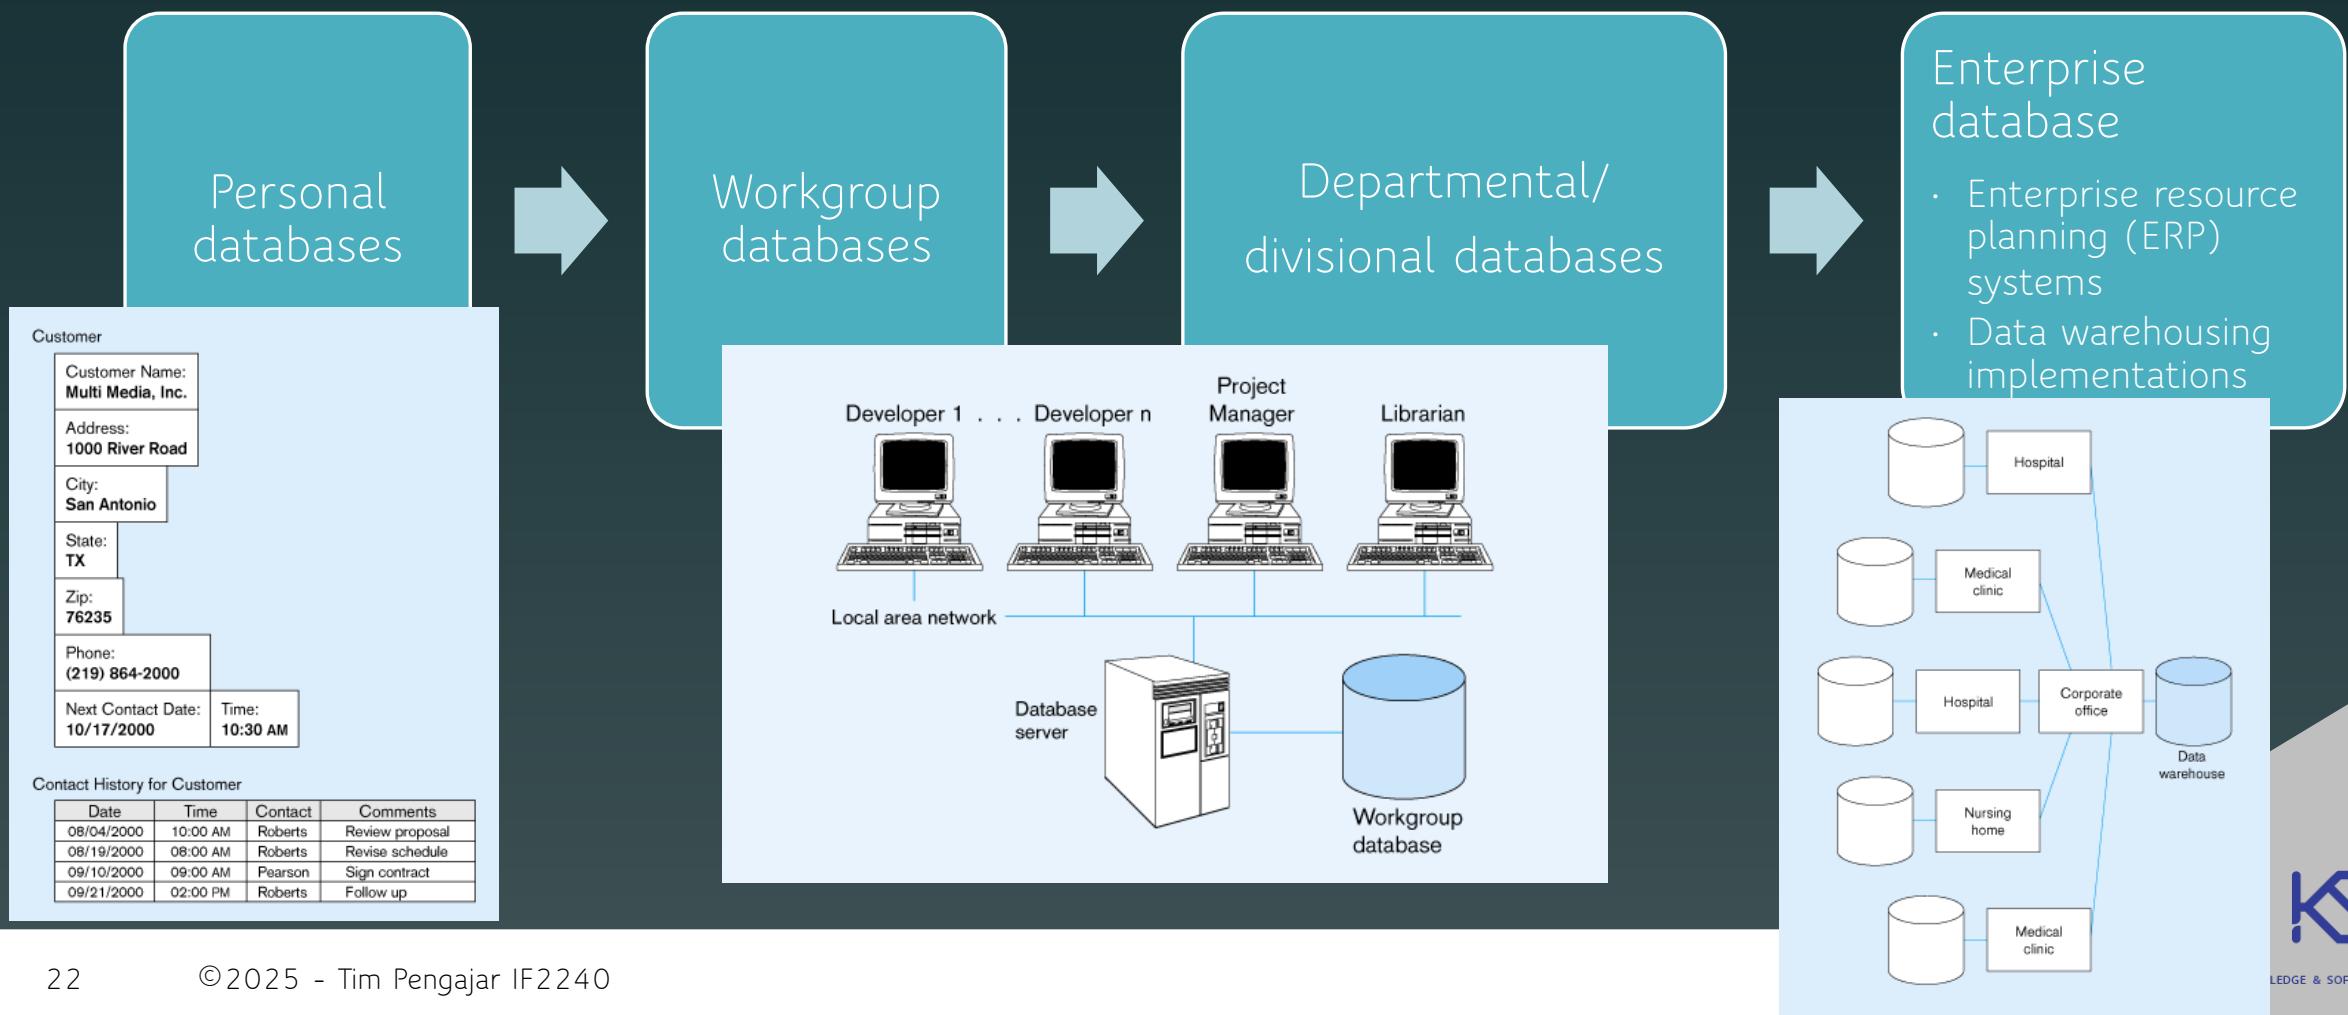

Data Administrators – personnel responsible for maintaining the database

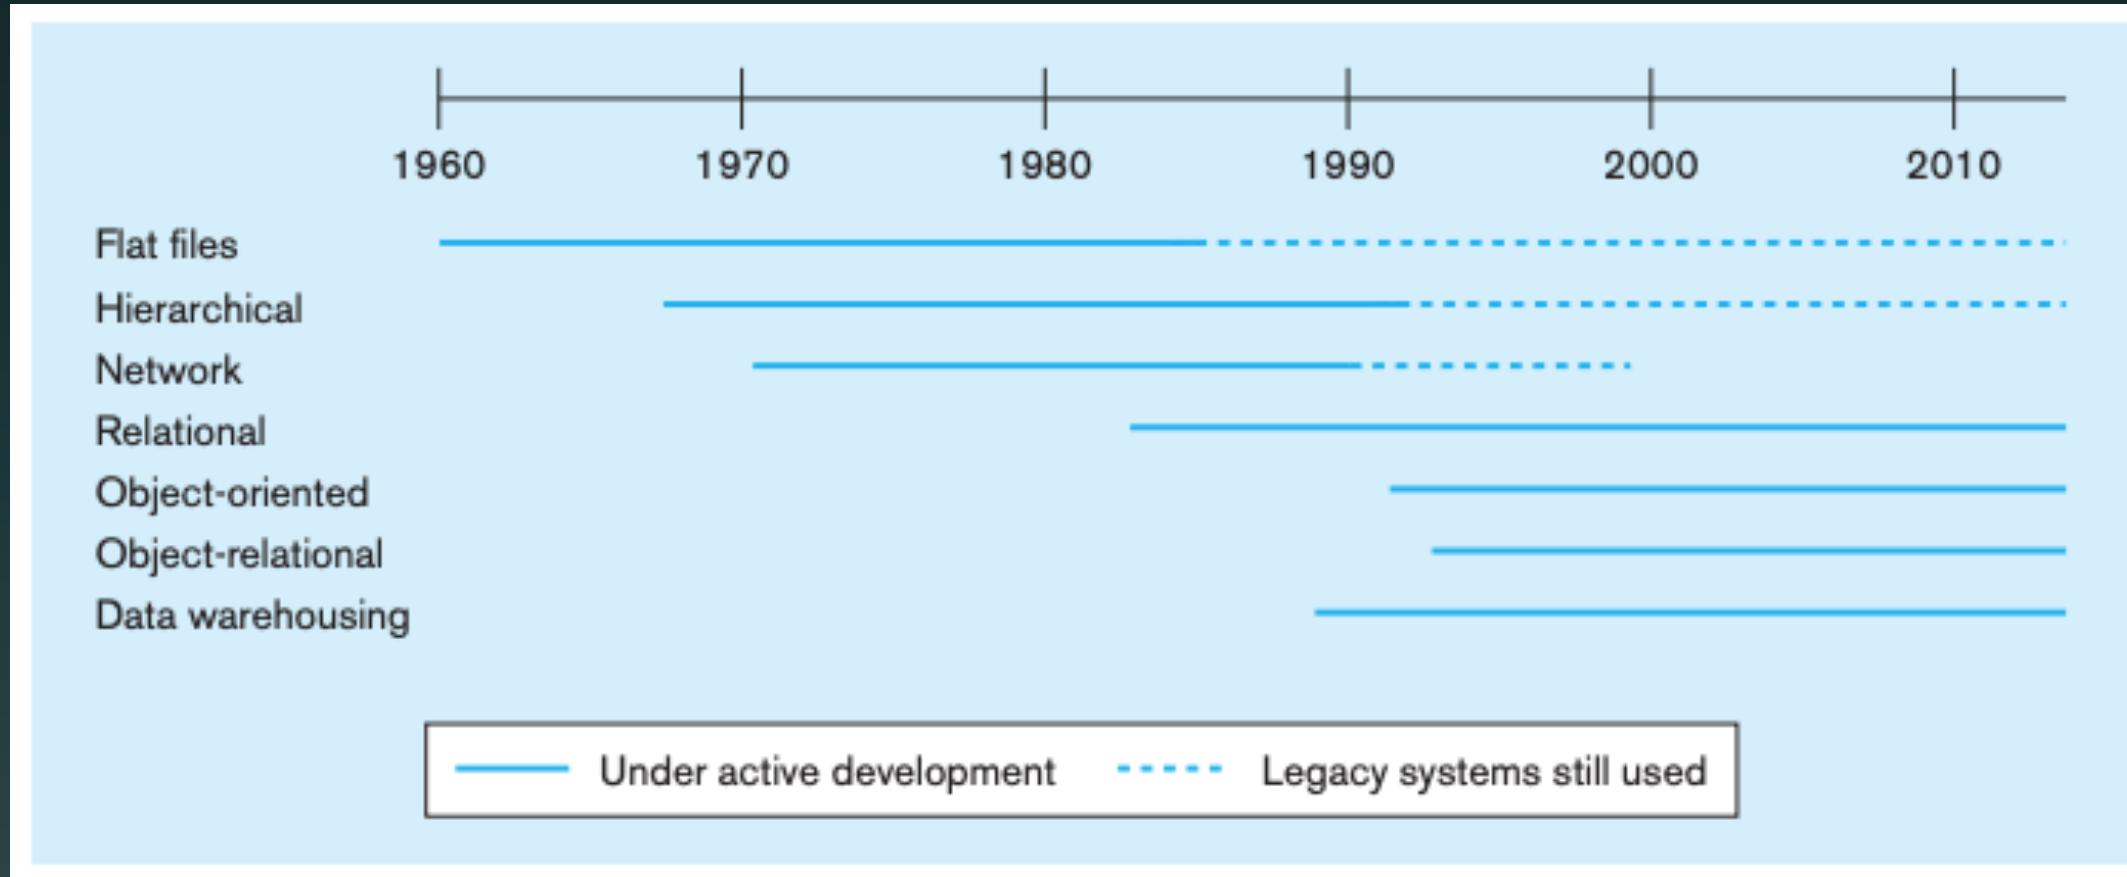

System Developers – personnel responsible for designing databases and software

End Users – people who use the applications and databases

The Range of Database Applications

Evolution of Database Technologies

More on Database Approach

Modified from Silberschatz's slides, Database System Concept, 7th edition

KNOWLEDGE & SOFTWARE ENGINEERING

Levels of Abstraction

Physical level: describes how a record is stored.

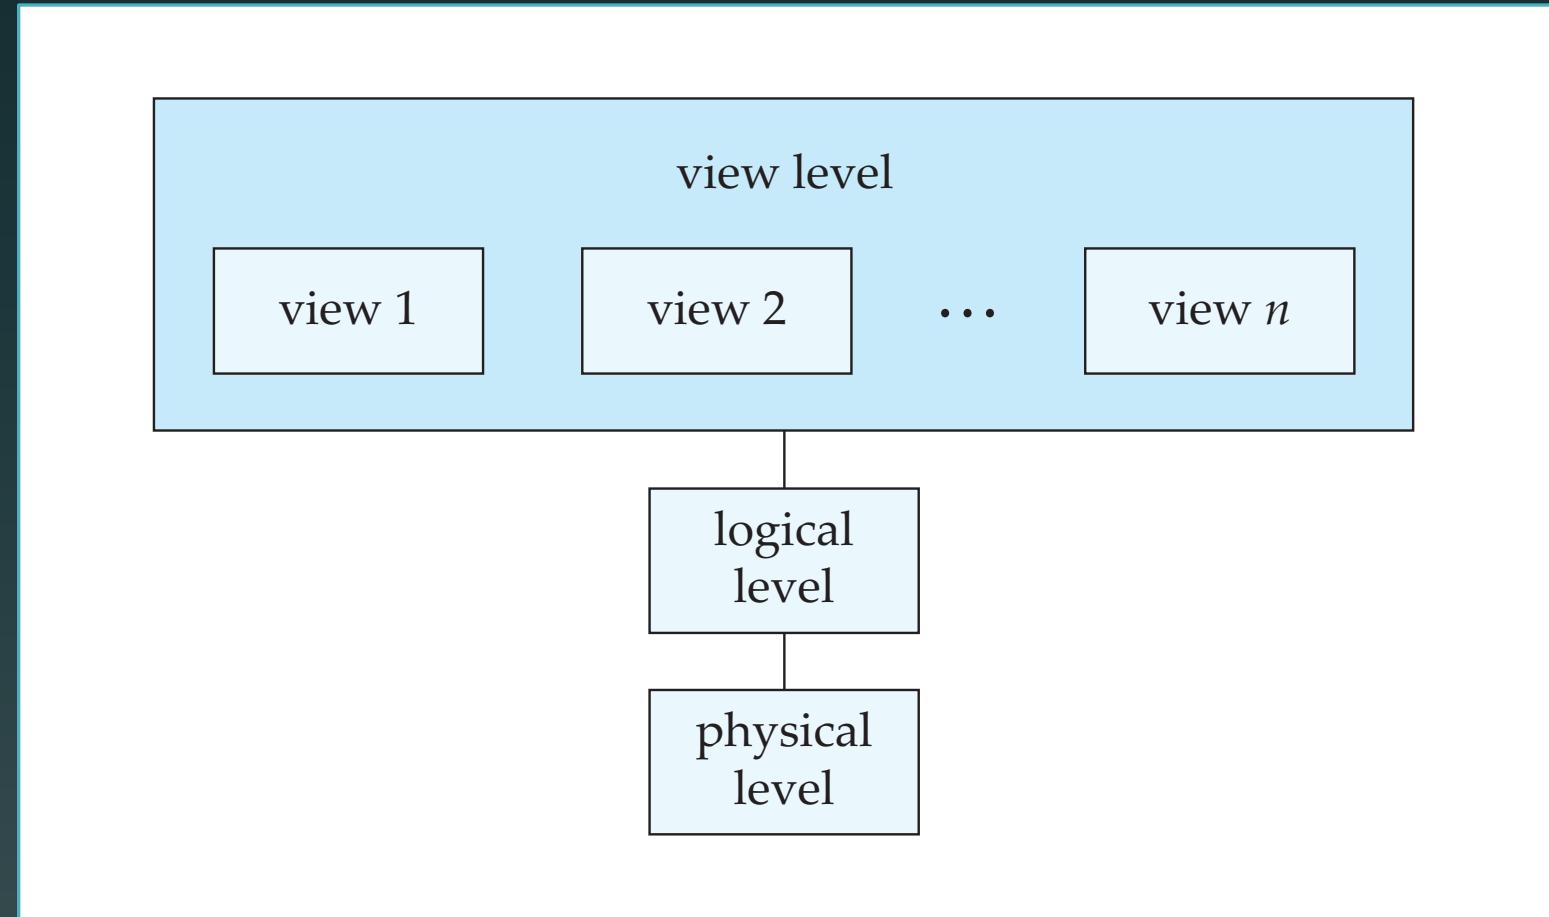

Logical level: describes data stored in database, and the relationships among the data.

```
type instructor = record  
    ID : string;  
    name : string;  
    dept_name : string;  
    salary : integer;  
end;
```

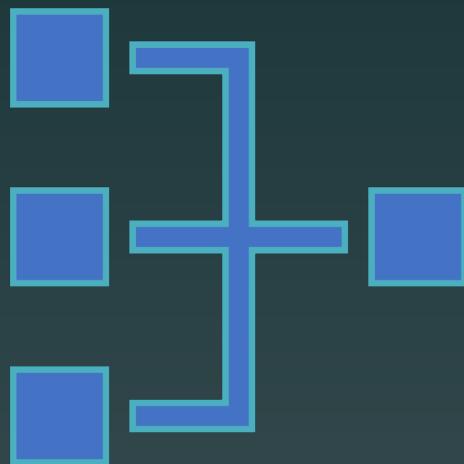

View level: application programs hide details of data types. Views can also hide information (such as an employee's salary) for security purposes.

View of Data

An architecture for a database system
(ANSI/SPARC Architecture)

Physical Data Independence

Physical Data Independence - the ability to modify the physical schema without changing the logical schema

- Applications depend on the logical schema
- In general, the interfaces between the various levels and components should be well defined so that changes in some parts do not seriously influence others.

Instances and Schemas

Schema : structure of the database

Logical Schema – the overall logical structure of the database

Physical Schema – the overall physical structure of the database

Instance : the actual content of the database at a particular point in time

Similar to types and variables in programming languages

Data Definition Language (DDL)

Specification notation for defining the database schema

Example: `create table instructor (
 ID char(5),
 name varchar(20),
 dept_name varchar(20),
 salary numeric(8,2))`

DDL compiler generates a set of table templates stored in a *data dictionary* - contains metadata (i.e., data about data)

- Database schema
- Integrity constraints
 - Primary key (ID uniquely identifies instructors)
- Authorization
- Who can access what

Data Manipulation Language (DML)

Language for accessing and updating the data organized by the appropriate data model

There are basically two types of data-manipulation language

- **Procedural DML** -- require a user to specify what data are needed and how to get those data.
- **Declarative DML** -- require a user to specify what data are needed without specifying how to get those data.

SQL Query Language

SQL query language is nonprocedural. A query takes as input several tables (possibly only one) and always returns a single table.

Example to find all instructors in Comp. Sci. dept

```
select name  
from instructor  
where dept_name = 'Comp. Sci.'
```

Application programs generally access databases through one of

- Language extensions to allow embedded SQL
- Application program interface (e.g., ODBC/JDBC) which allow SQL queries to be sent to a database

Database Design

Logical Design – Deciding on the database schema. Database design requires that we find a “good” collection of relation schemas.

Business decision – What attributes should we record?

Computer Science decision – What relation schemas should we have?

Physical Design – Deciding on the physical layout of the database

Database Management System

- A database management system is partitioned into modules that deal with each of the responsibilities of the overall system.
- The **functional components** of a database management system can be divided into:

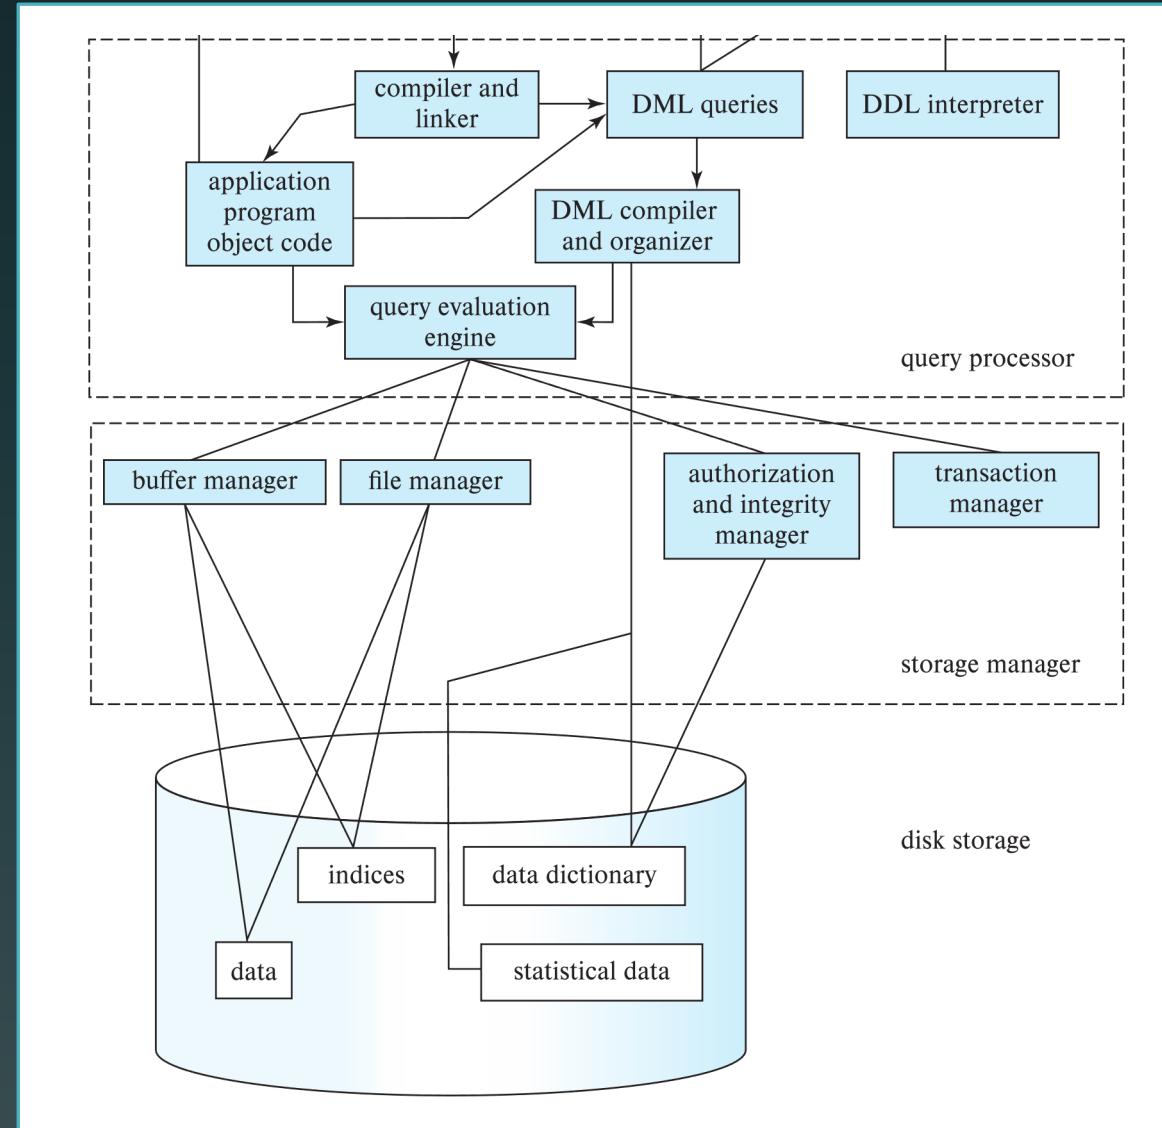

The storage manager

The query processor component

The transaction management component

A Database Management System Architecture

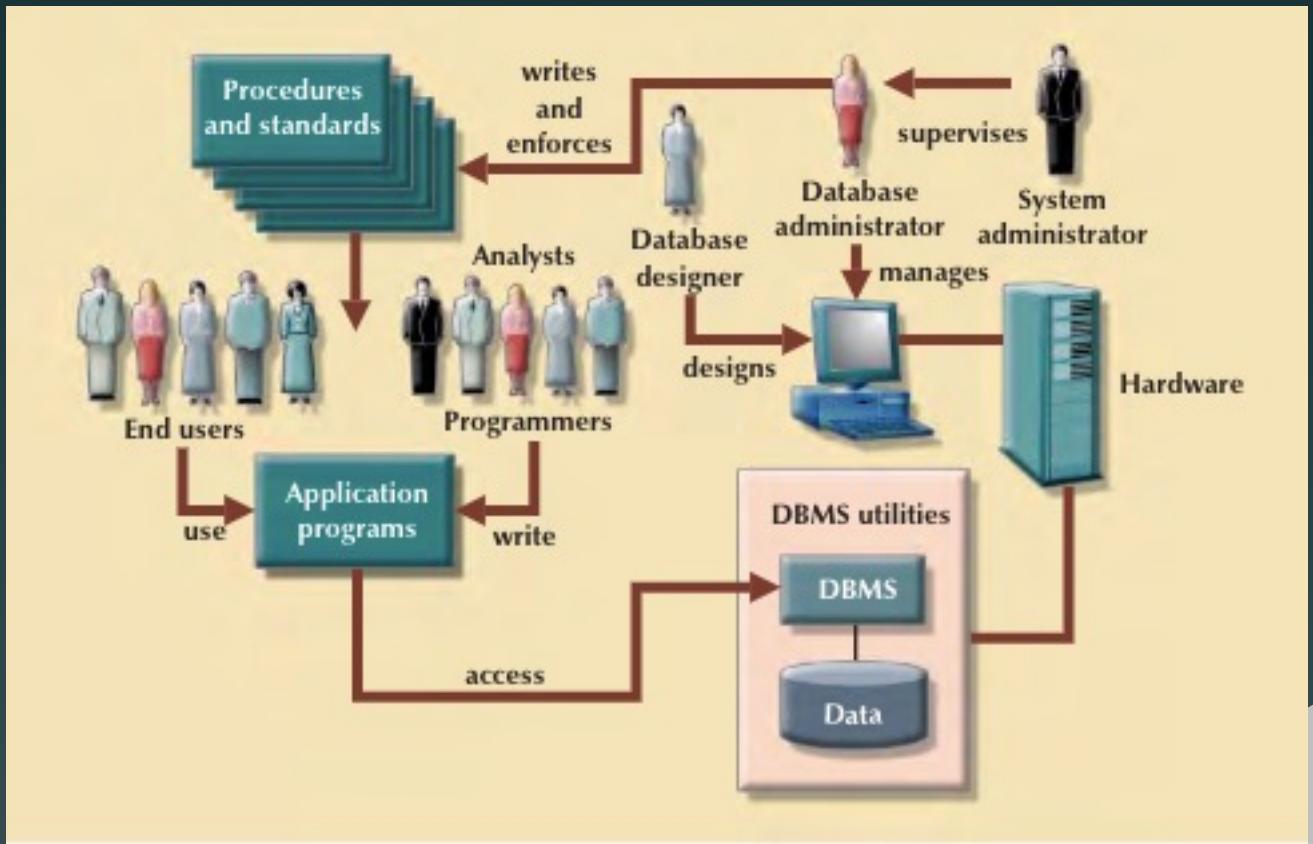

on a centralized server machine

The Database System Environment

Database System refers to an organization of components that define and regulate the collection, storage, management, and use of data within a database environment.

The database system is composed of the five major parts: hardware, software, people, procedures, and data.

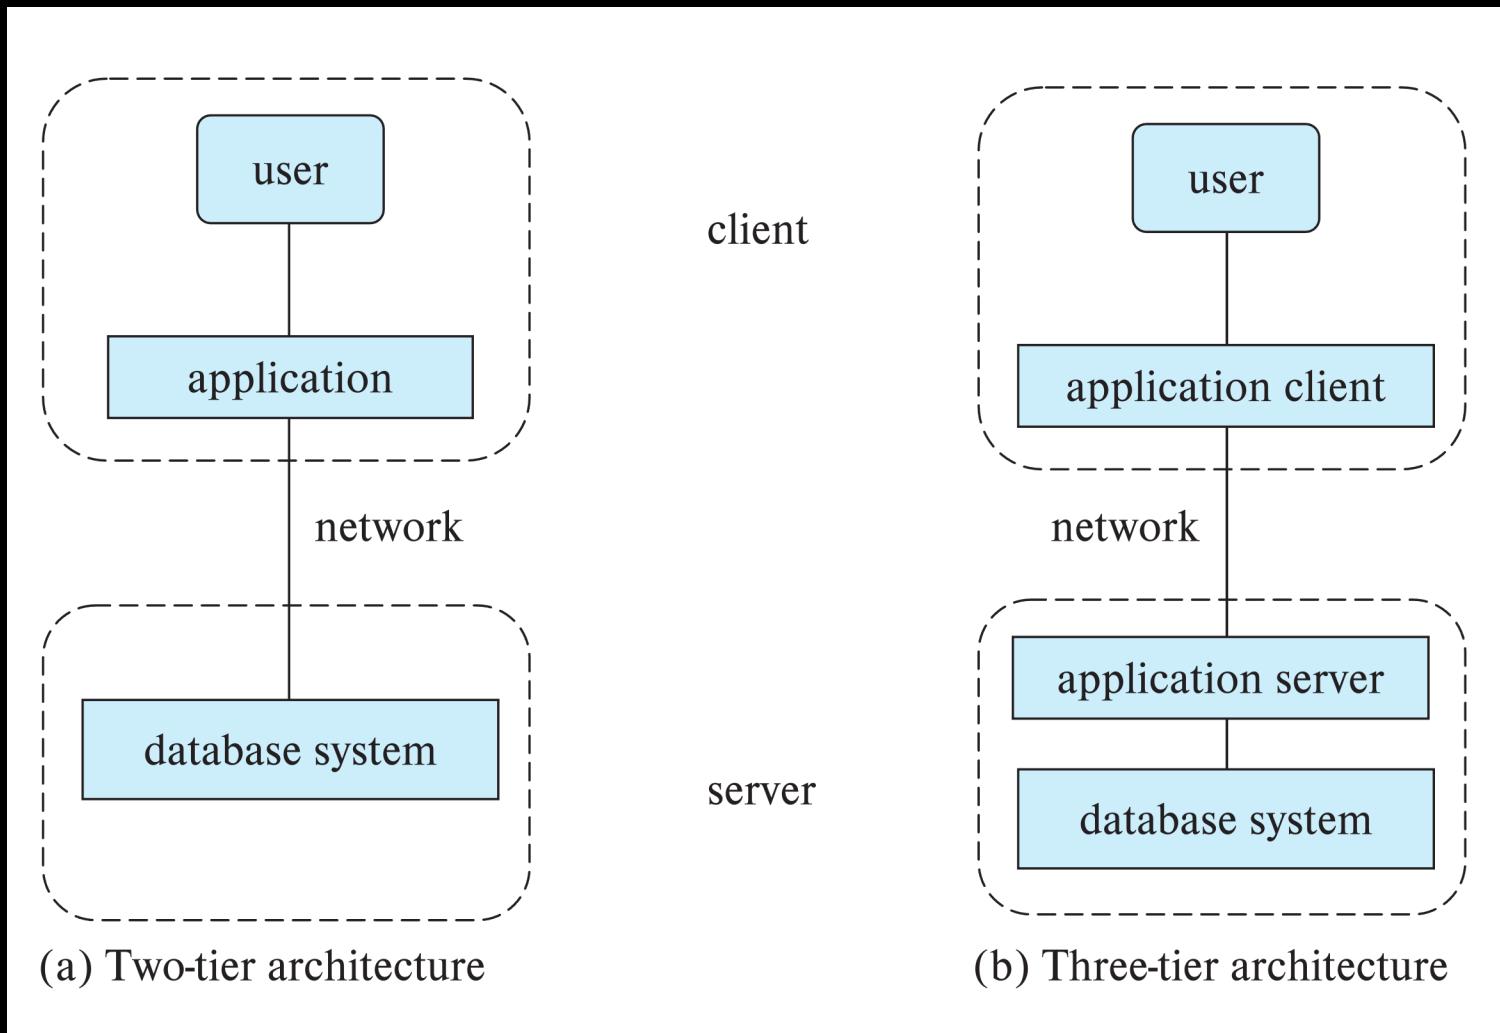

C. Coronel, S. Morris, P. Rob, 'Database System: Design, Implementation, and Management', Ninth Edition, Cengage Learning

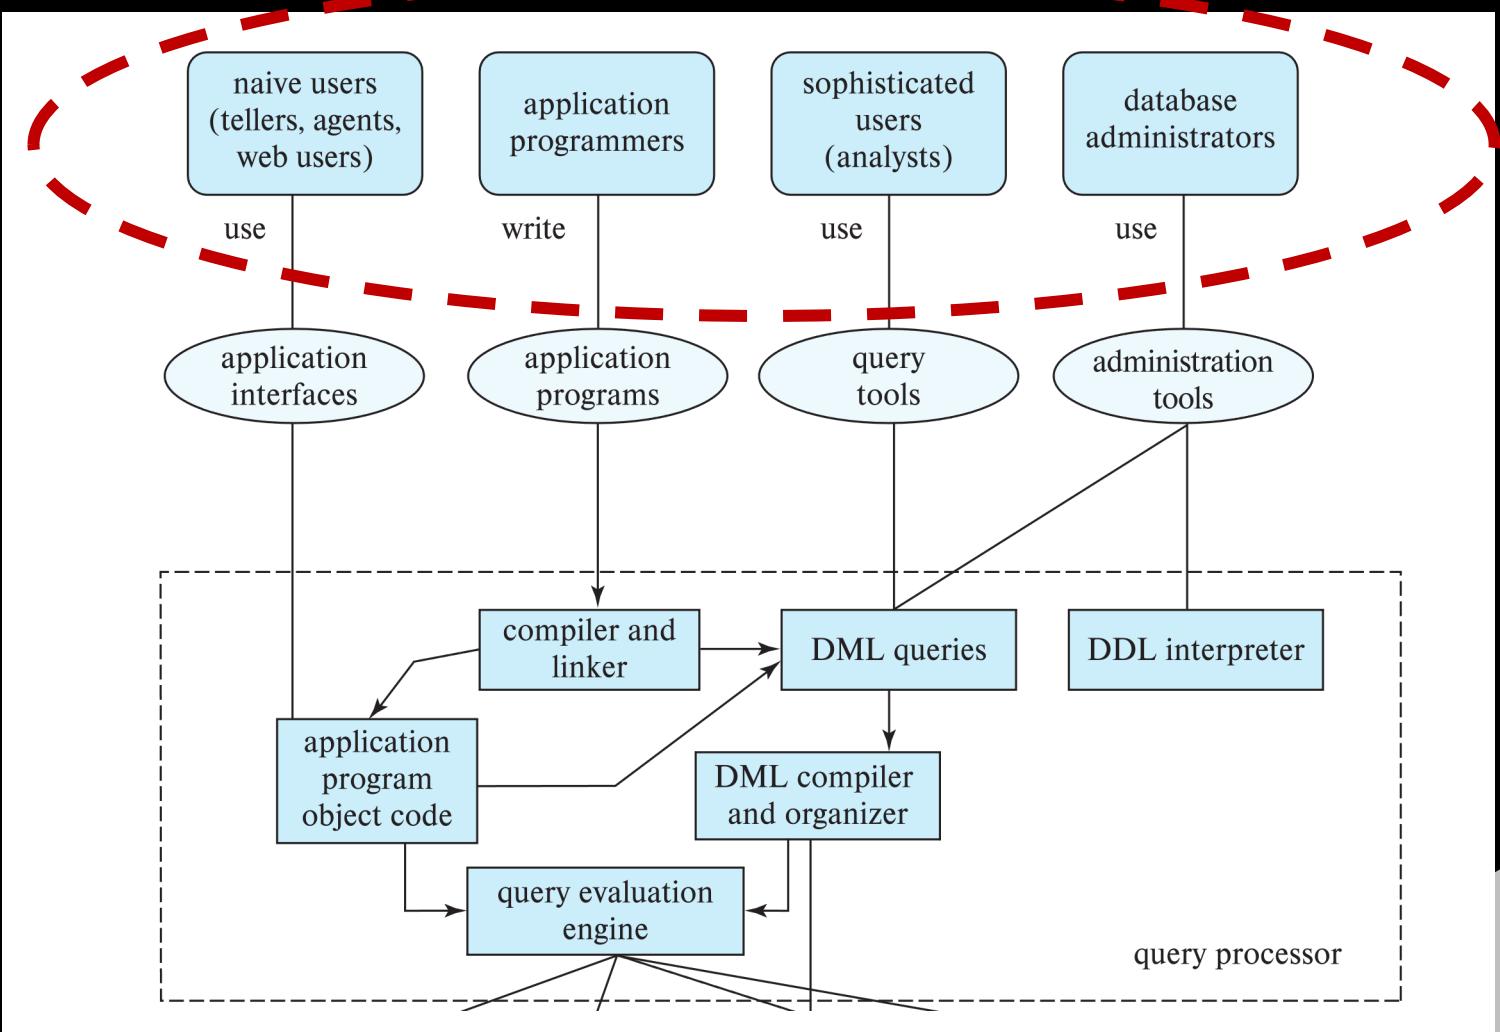

Database Applications Architecture

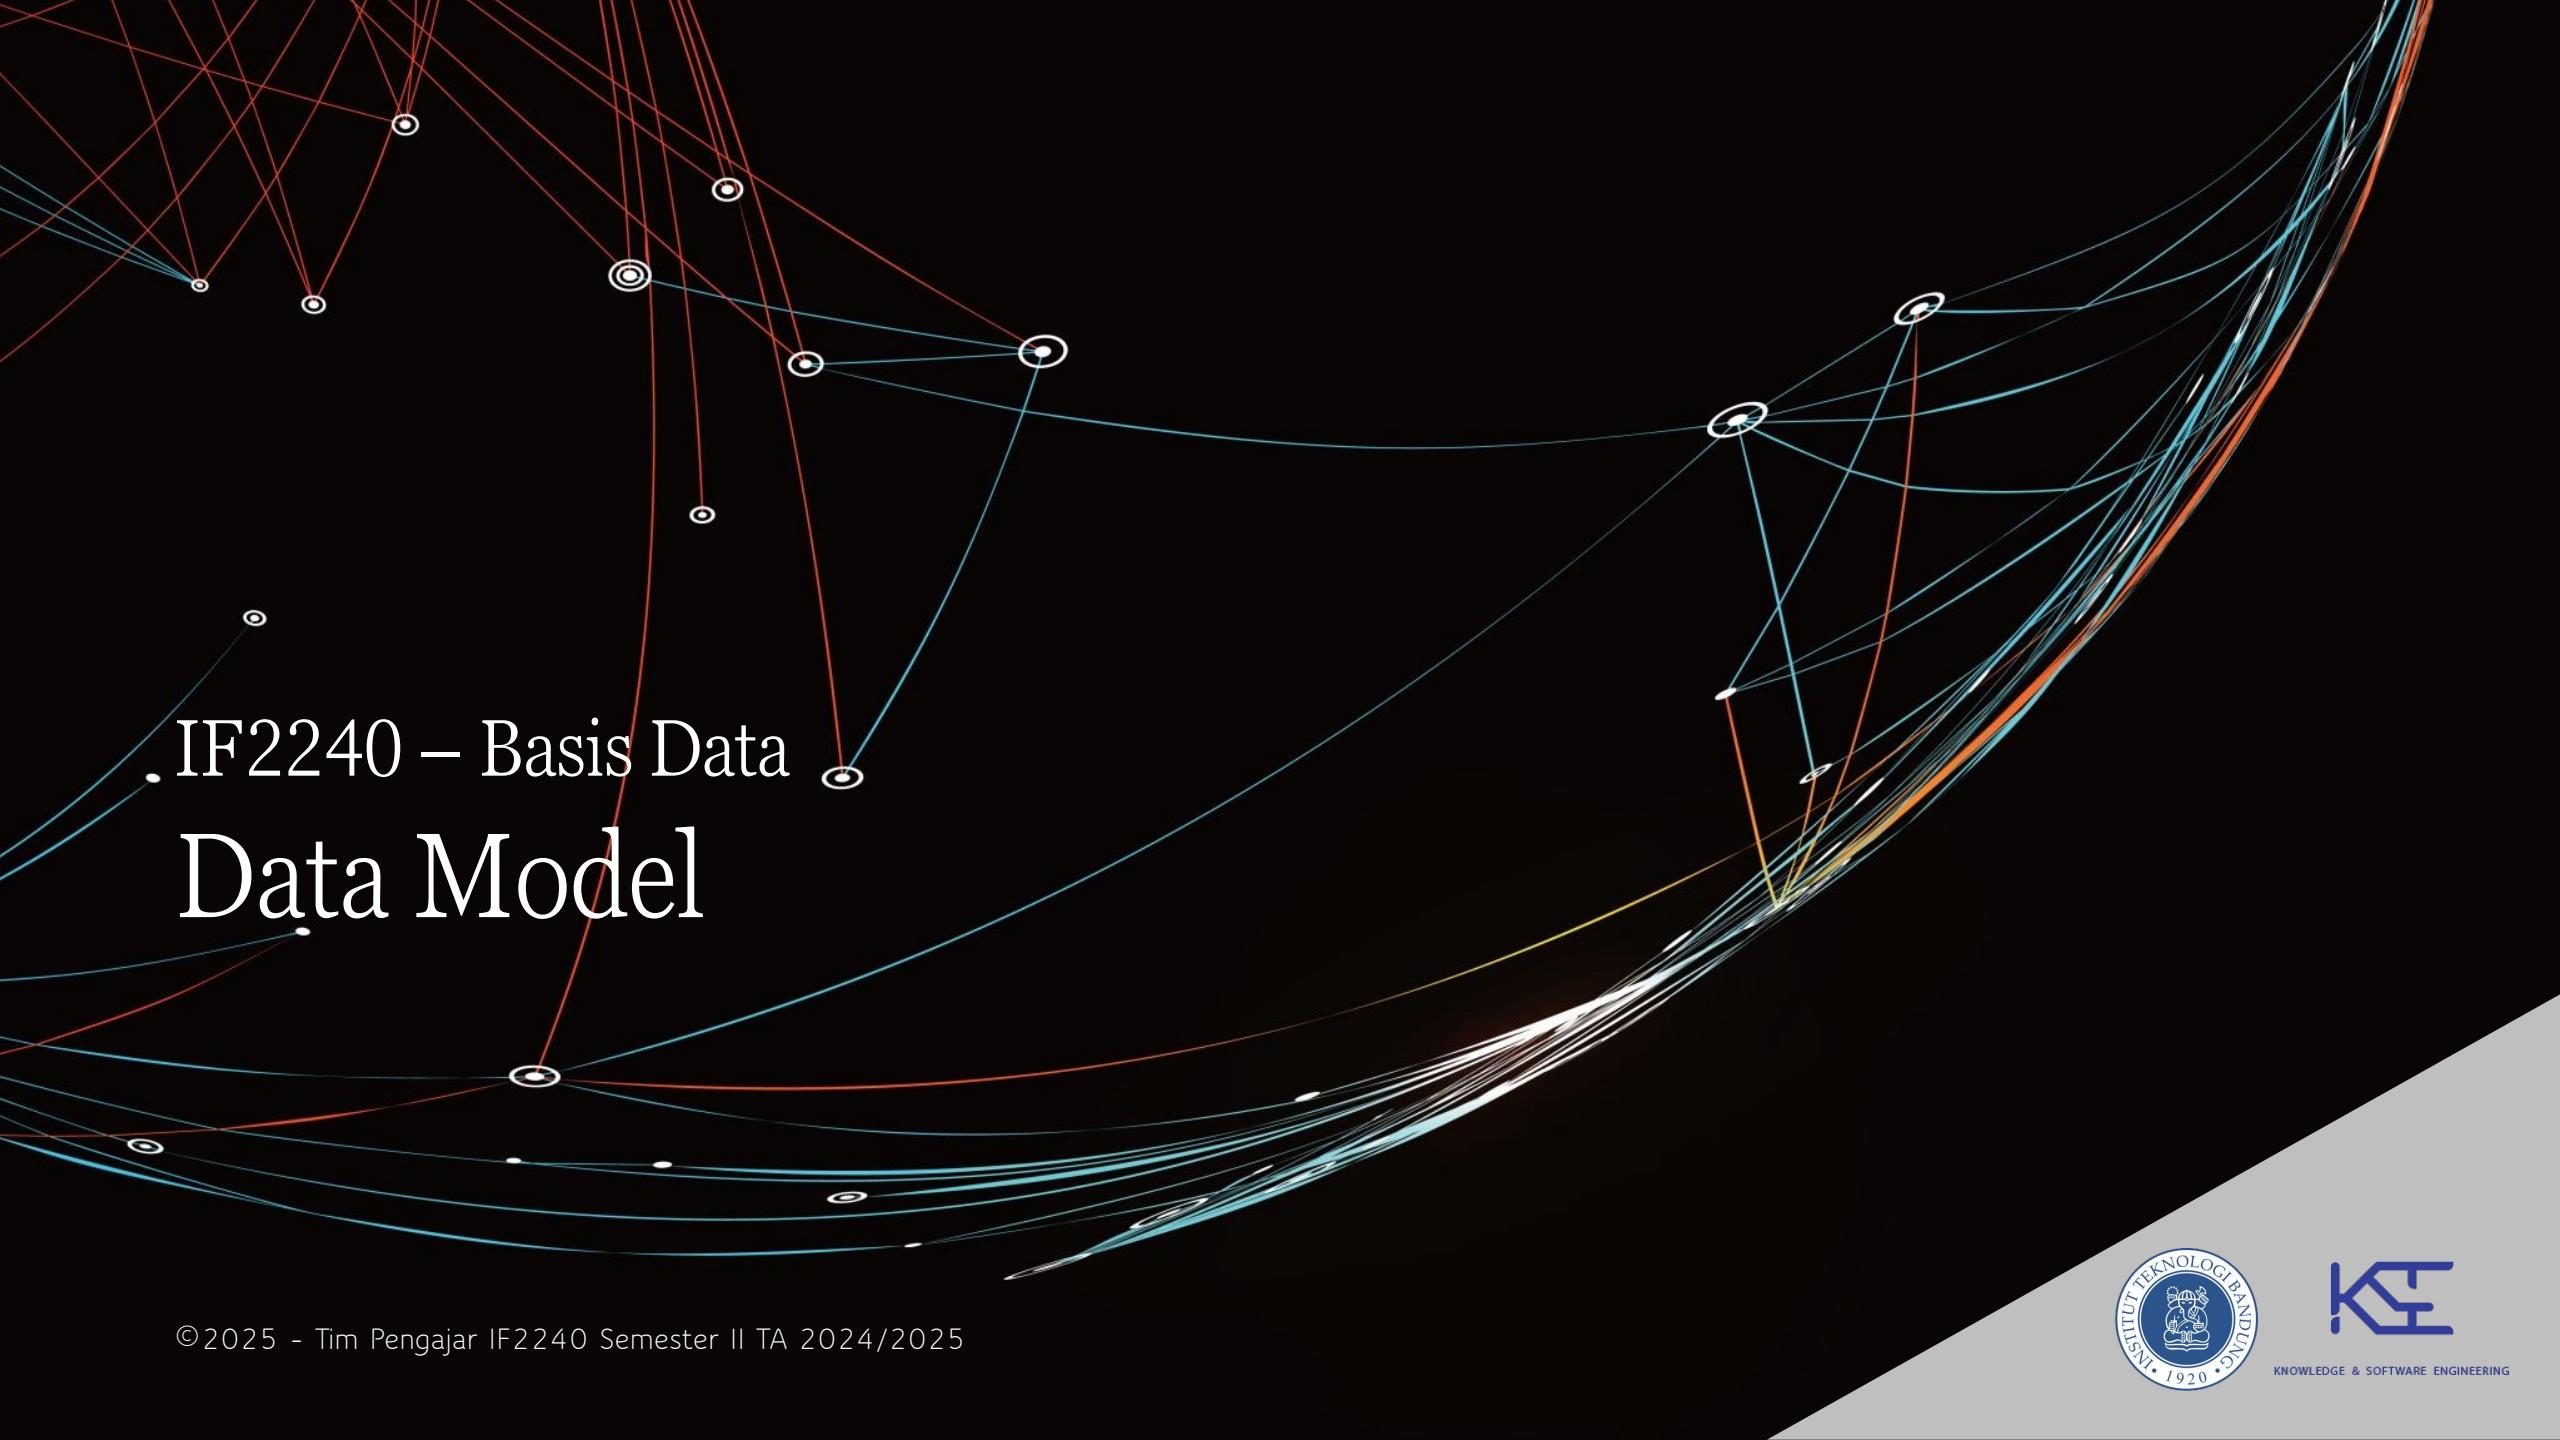

Two-tier architecture -- the application resides at the client machine, where it invokes database system functionality at the server machine

Three-tier architecture -- the client machine acts as a front end and does not contain any direct database calls.

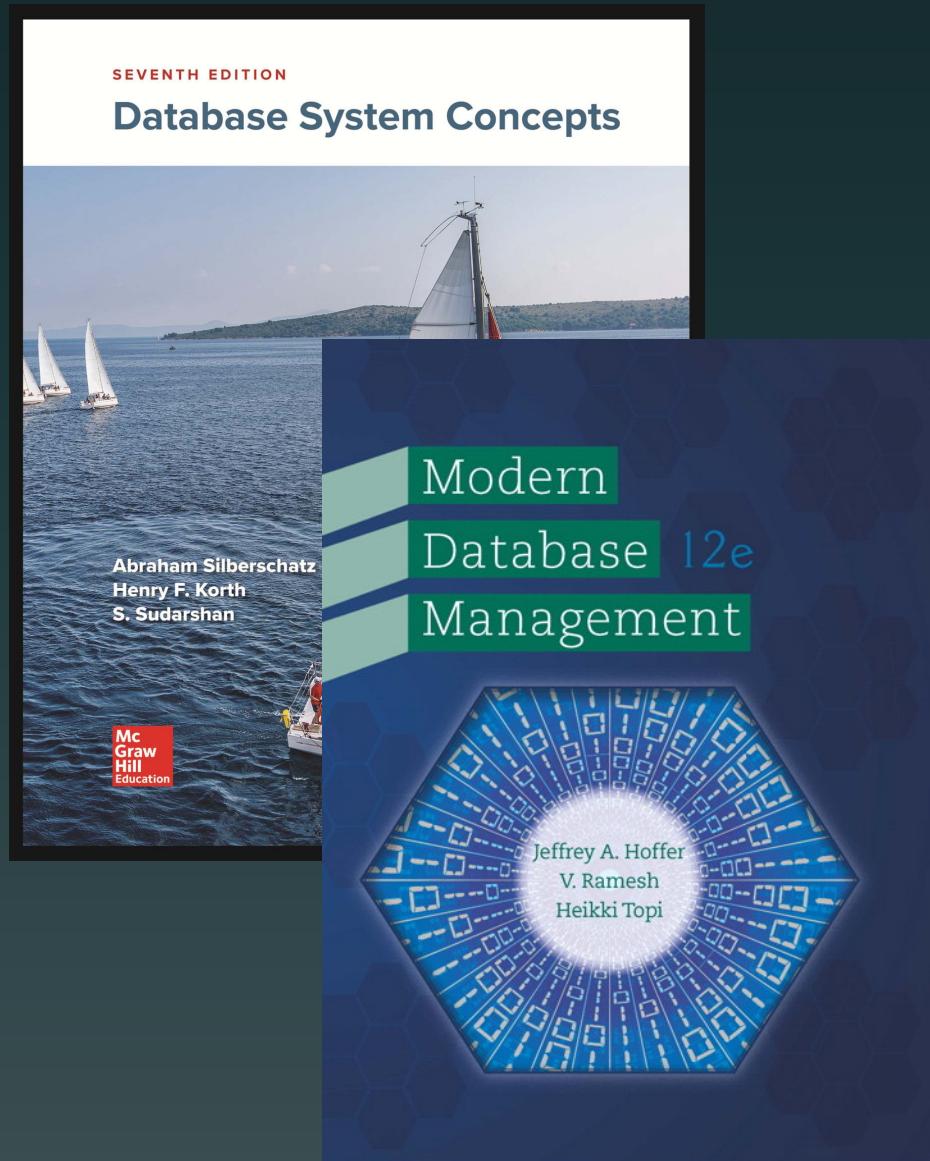

Database Users

- Chapter 1: Introduction

Jeffrey A. Hoffer, Mary B. Prescott, Heikki Topi : “Modern Database Management”, 12th Edition

- Chapter 1: The Database Environment and Development Process

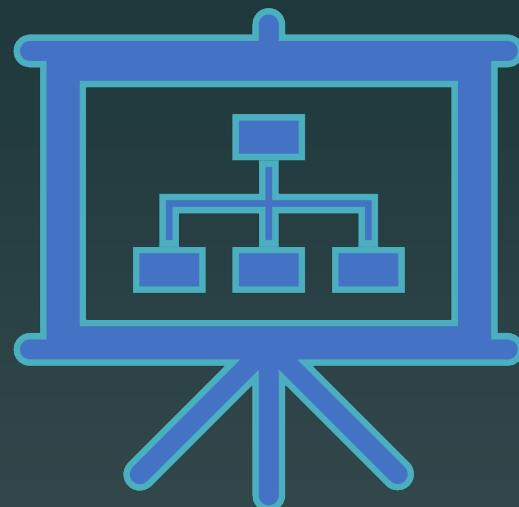

Data Modeling (1/2)

- A technique aimed at optimizing the way that information is stored and used within an organization
 - Begins with the **identification** of the main data groups, continues by **defining** the detailed content of each of these groups.
 - Result: **structured definitions** for all of the information that is stored and used within a given system.
- An **essential precursor** to analysis, design, maintenance & documentation and improving the performance of an existing system.

Data Modeling (2/2)

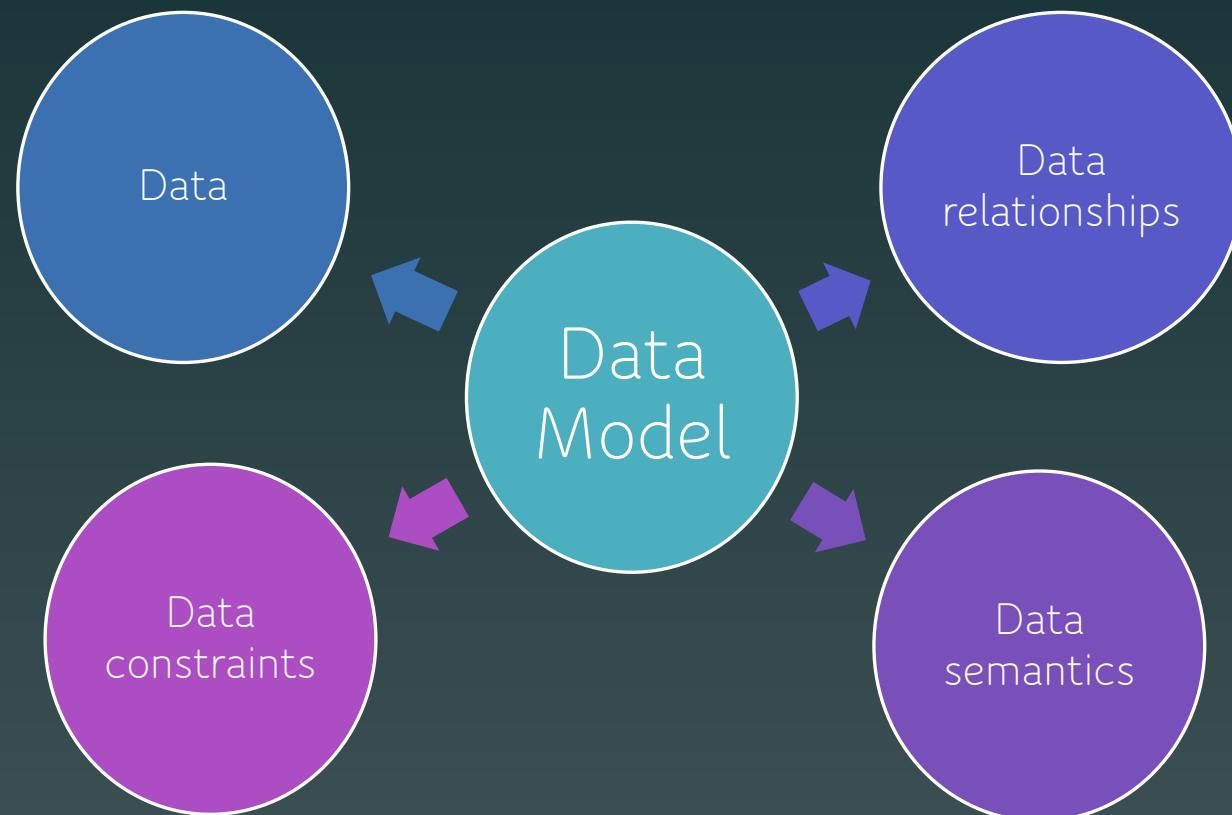

There are three different types of data models produced while progressing **from requirements to the actual database**.

- **Conceptual data model**: a set of technology independent specifications about the data and is used to discuss initial requirements with the business stakeholders.
- **Logical data model**: the structures of the data that can be implemented in databases.
- **Physical data model**: that organizes the data into tables, and accounts for access, performance and storage details.

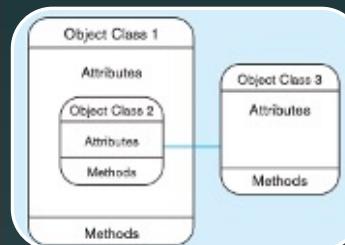

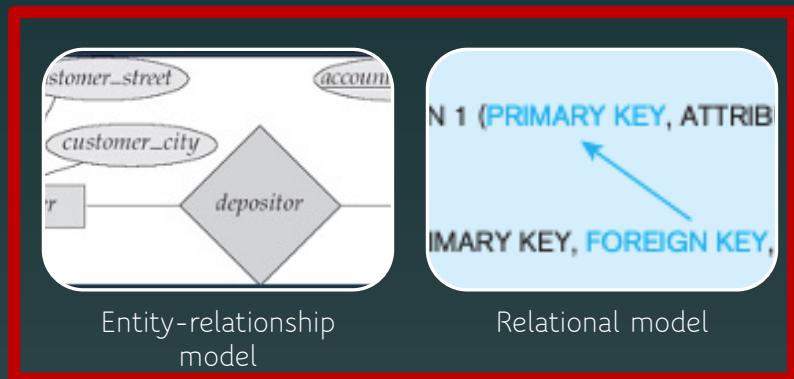

Data Model (1/2)

A collection of tools for describing:

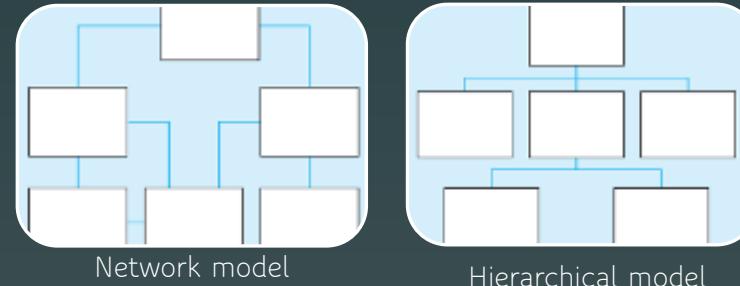

Data Model (2/2)

Types of data model:

```
>>>
<account>
<account-number>A-101</account-number>
<bran>
```

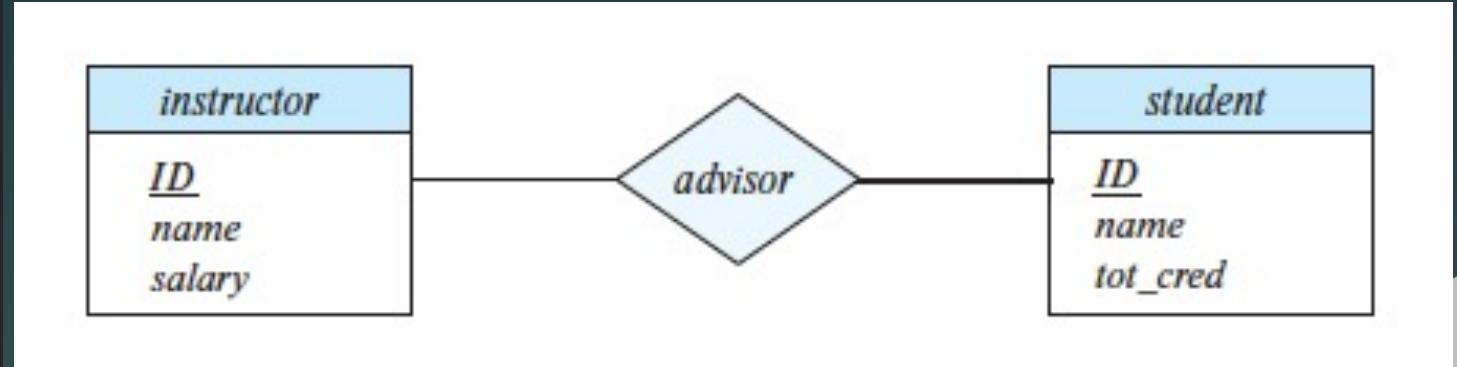

Semi-structured data model (XML)

Older data models

Entity Relationship Model

- Widely used for database design
 - Database design in E-R model usually converted into design in Relational Model
- Models an enterprise as a collection of *entities* and *relationships*
 - **Entity**: a “thing” or “object” in the enterprise that is distinguishable from other objects
 - **Relationship**: an association among several entities
- Represented diagrammatically by an *entity-relationship diagram* (ERD)

KNOWLEDGE & SOFTWARE ENGINEERING

Relational Model

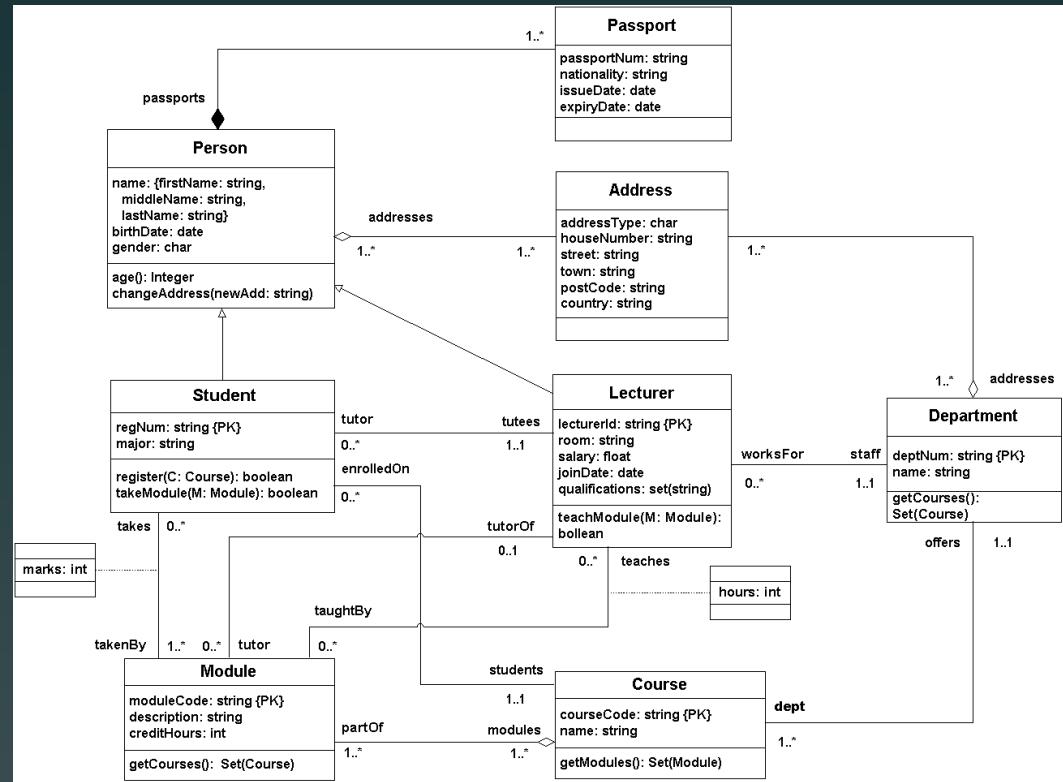

- Consist of collection of tables to represent data and the relationship among those data
- Example of tabular data in the relational model

Attributes

<i>customer_id</i>	<i>customer_name</i>	<i>customer_street</i>	<i>customer_city</i>	<i>account_number</i>
192-83-7465	Johnson	12 Alma St.	Palo Alto	A-101
192-83-7465	Johnson	12 Alma St.	Palo Alto	A-201
677-89-9011	Hayes	3 Main St.	Harrison	A-102
182-73-6091	Turner	123 Putnam St.	Stamford	A-305
321-12-3123	Jones	100 Main St.	Harrison	A-217
336-66-9999	Lindsay	175 Park Ave.	Pittsfield	A-222
019-28-3746	Smith	72 North St.	Rye	A-201

Object-Oriented Data Model

- Adaptation of the object-oriented programming paradigm (e.g. Smalltalk, C++) to database systems
- The *object-oriented paradigm* is based on *encapsulating code and data related to an object into single unit*

Object Structure

```
class Person {  
    /* variable */  
    Name      name;  
    date     birthDate;  
    string   address;  
    char     gender;  
  
    /* messages */  
    int       age();  
    int       changeAddress(string newAdd);  
    Name     getName();  
    date     getBirthDate();  
    string   getAddress();  
    char     getGender();  
  
};  
  
string getAddress() {  
    return address;  
}
```

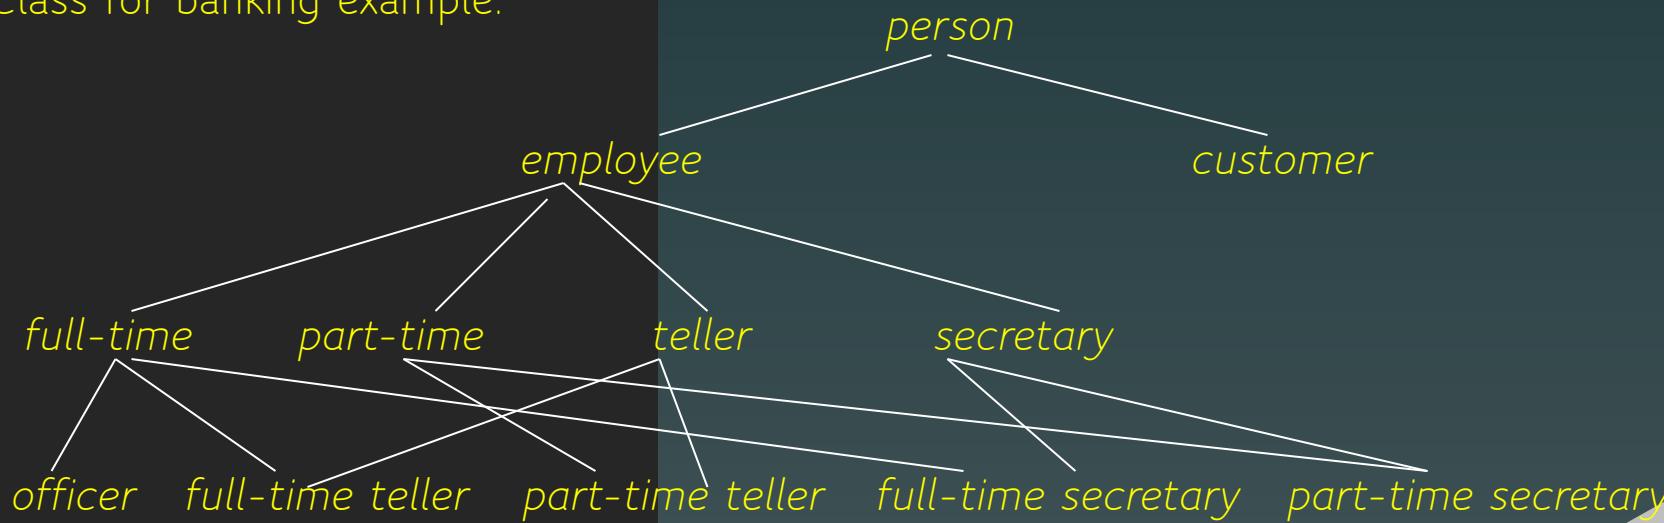

An object has associated with it:

- A **set of variables** that contain the data for the object. The value of each variable is itself an object.
- A **set of messages** to which the object responds; each message may have zero, one, or more *parameters*.
- A **set of methods**, each of which is a body of code to implement a message; a method returns a value as the *response* to the message

Object- Relational Data Model

- Extend the relational data model by including object orientation and a richer type system including collection types
 - Object orientation provides inheritance with subtypes and sub tables
 - Collection types include nested relations, sets, multisets, and arrays
- Preserve relational foundations, in particular the declarative access to data, while extending modeling power

Class for banking example:

Semi Structured Data Model (ex: XML)

- The ability to specify new tags, and to create nested tag structures made XML a great way to exchange **data**, not just documents
- XML has become the basis for all new generation data interchange formats.
- A wide variety of tools is available for parsing, browsing and querying XML documents/data

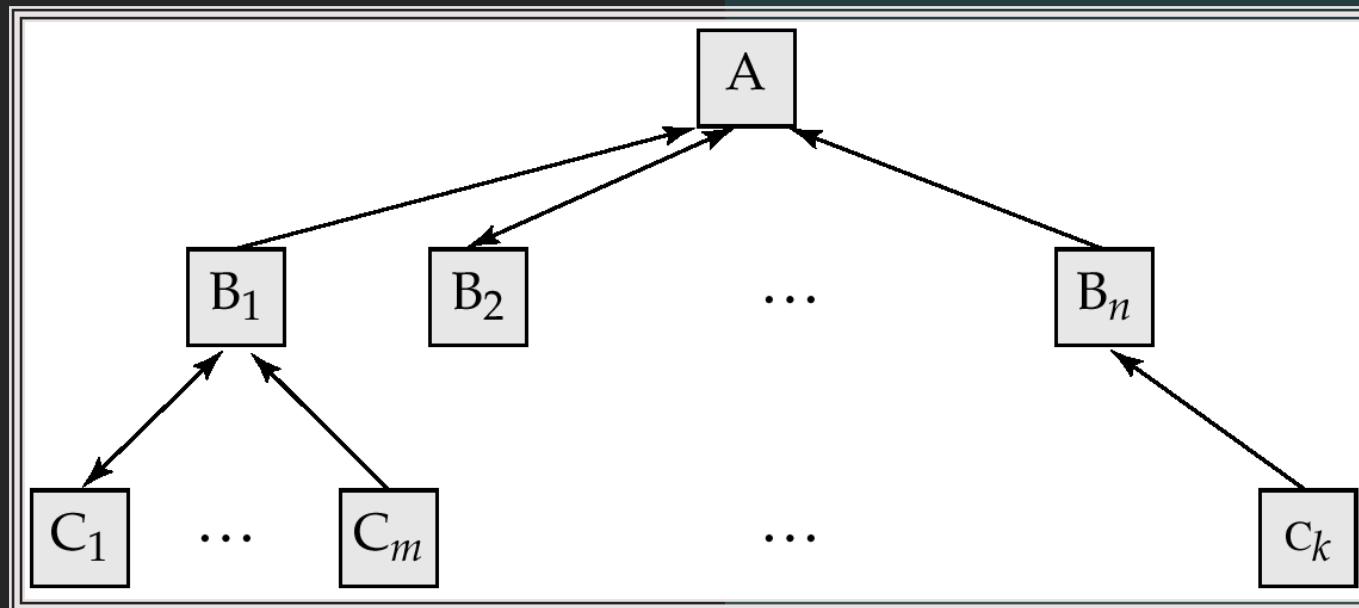

- Characteristics:
 - organized in semantic entities
 - similar entities are grouped together
 - entities in same group may not have same attributes
 - order of attributes not necessarily important
 - not all attributes may be required
 - size of same attributes in a group may differ
 - type of same attributes in a group may differ

→Self-describing, irregular data, no a priori structure

```
<bank>
  <account>
    <account-number>A-101</account-number>
    <branch-name>Downtown</branch-name>
    <balance>500</balance>
  </account>
  ...
  <customer>
    <customer-name>Johnson</customer-name>
    <customer-street>Alma</customer-street>
    <customer-city>Palo Alto</customer-city>
  </customer>
  ...
</bank>
```

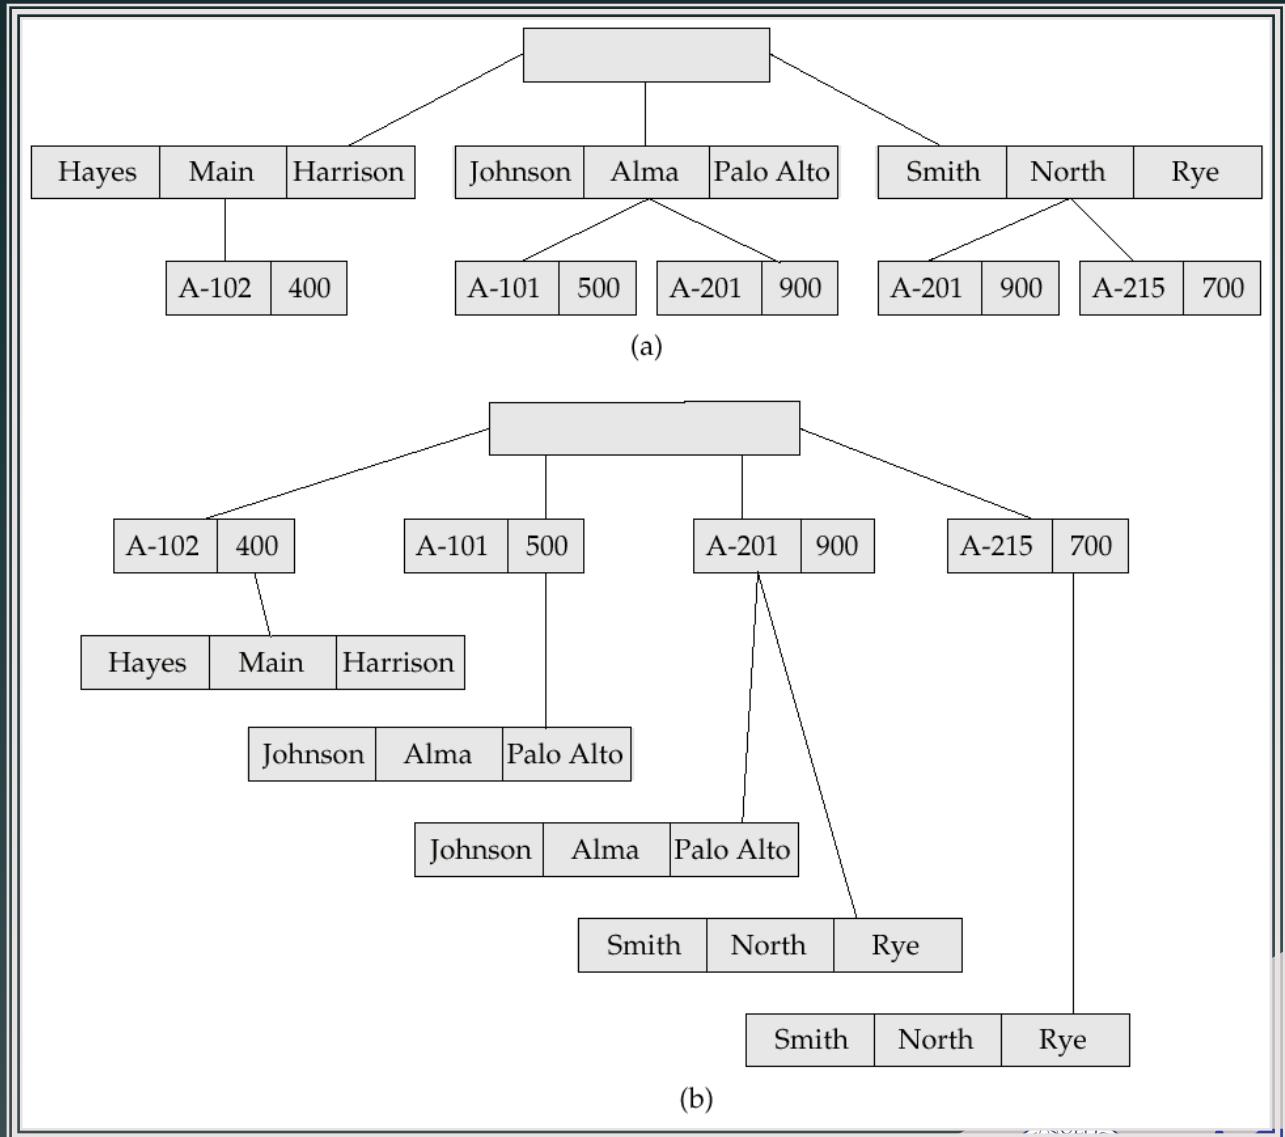

Hierarchical Model (1/2)

- World's leading mainframe hierarchical database system in the 1970s and early 1980s
- Database schema is represented as a collection of tree-structure diagrams
 - *Single* instance of a database tree
 - The root of this tree is a dummy node
 - The children of that node are actual instances of the appropriate record type
- The schema for a hierarchical database consists of
 - *boxes*, which correspond to record types
 - *lines*, which correspond to links
- Record types are organized in the form of a *rooted tree*

A parent *may* have an arrow pointing to a child, but a child *must* have an arrow pointing to its parent

Hierarchical Model (2/2)

Network Model (1/2)

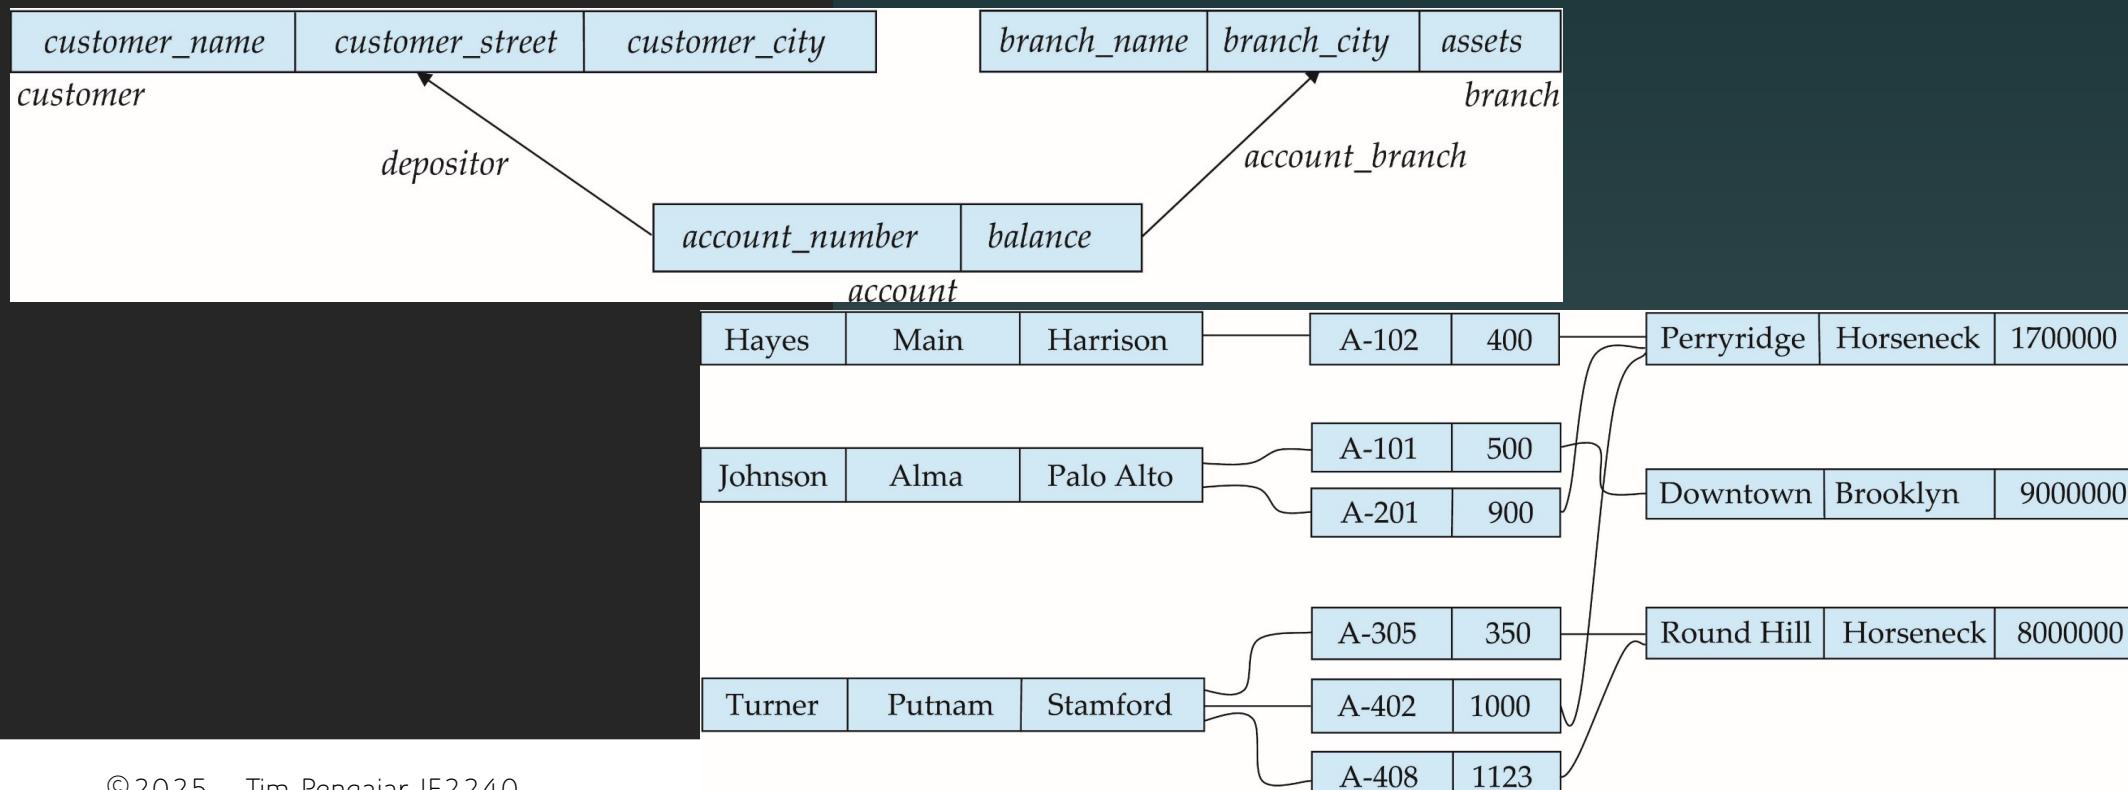

- Data are represented by collections of *records*.
 - similar to an entity in the E-R model
 - Records and their fields are represented as *record type*
- Relationships among data are represented by *links*
 - similar to a restricted (binary) form of an E-R relationship
 - restrictions on links depend on whether the relationship is many-many, many-to-one, or one-to-one.

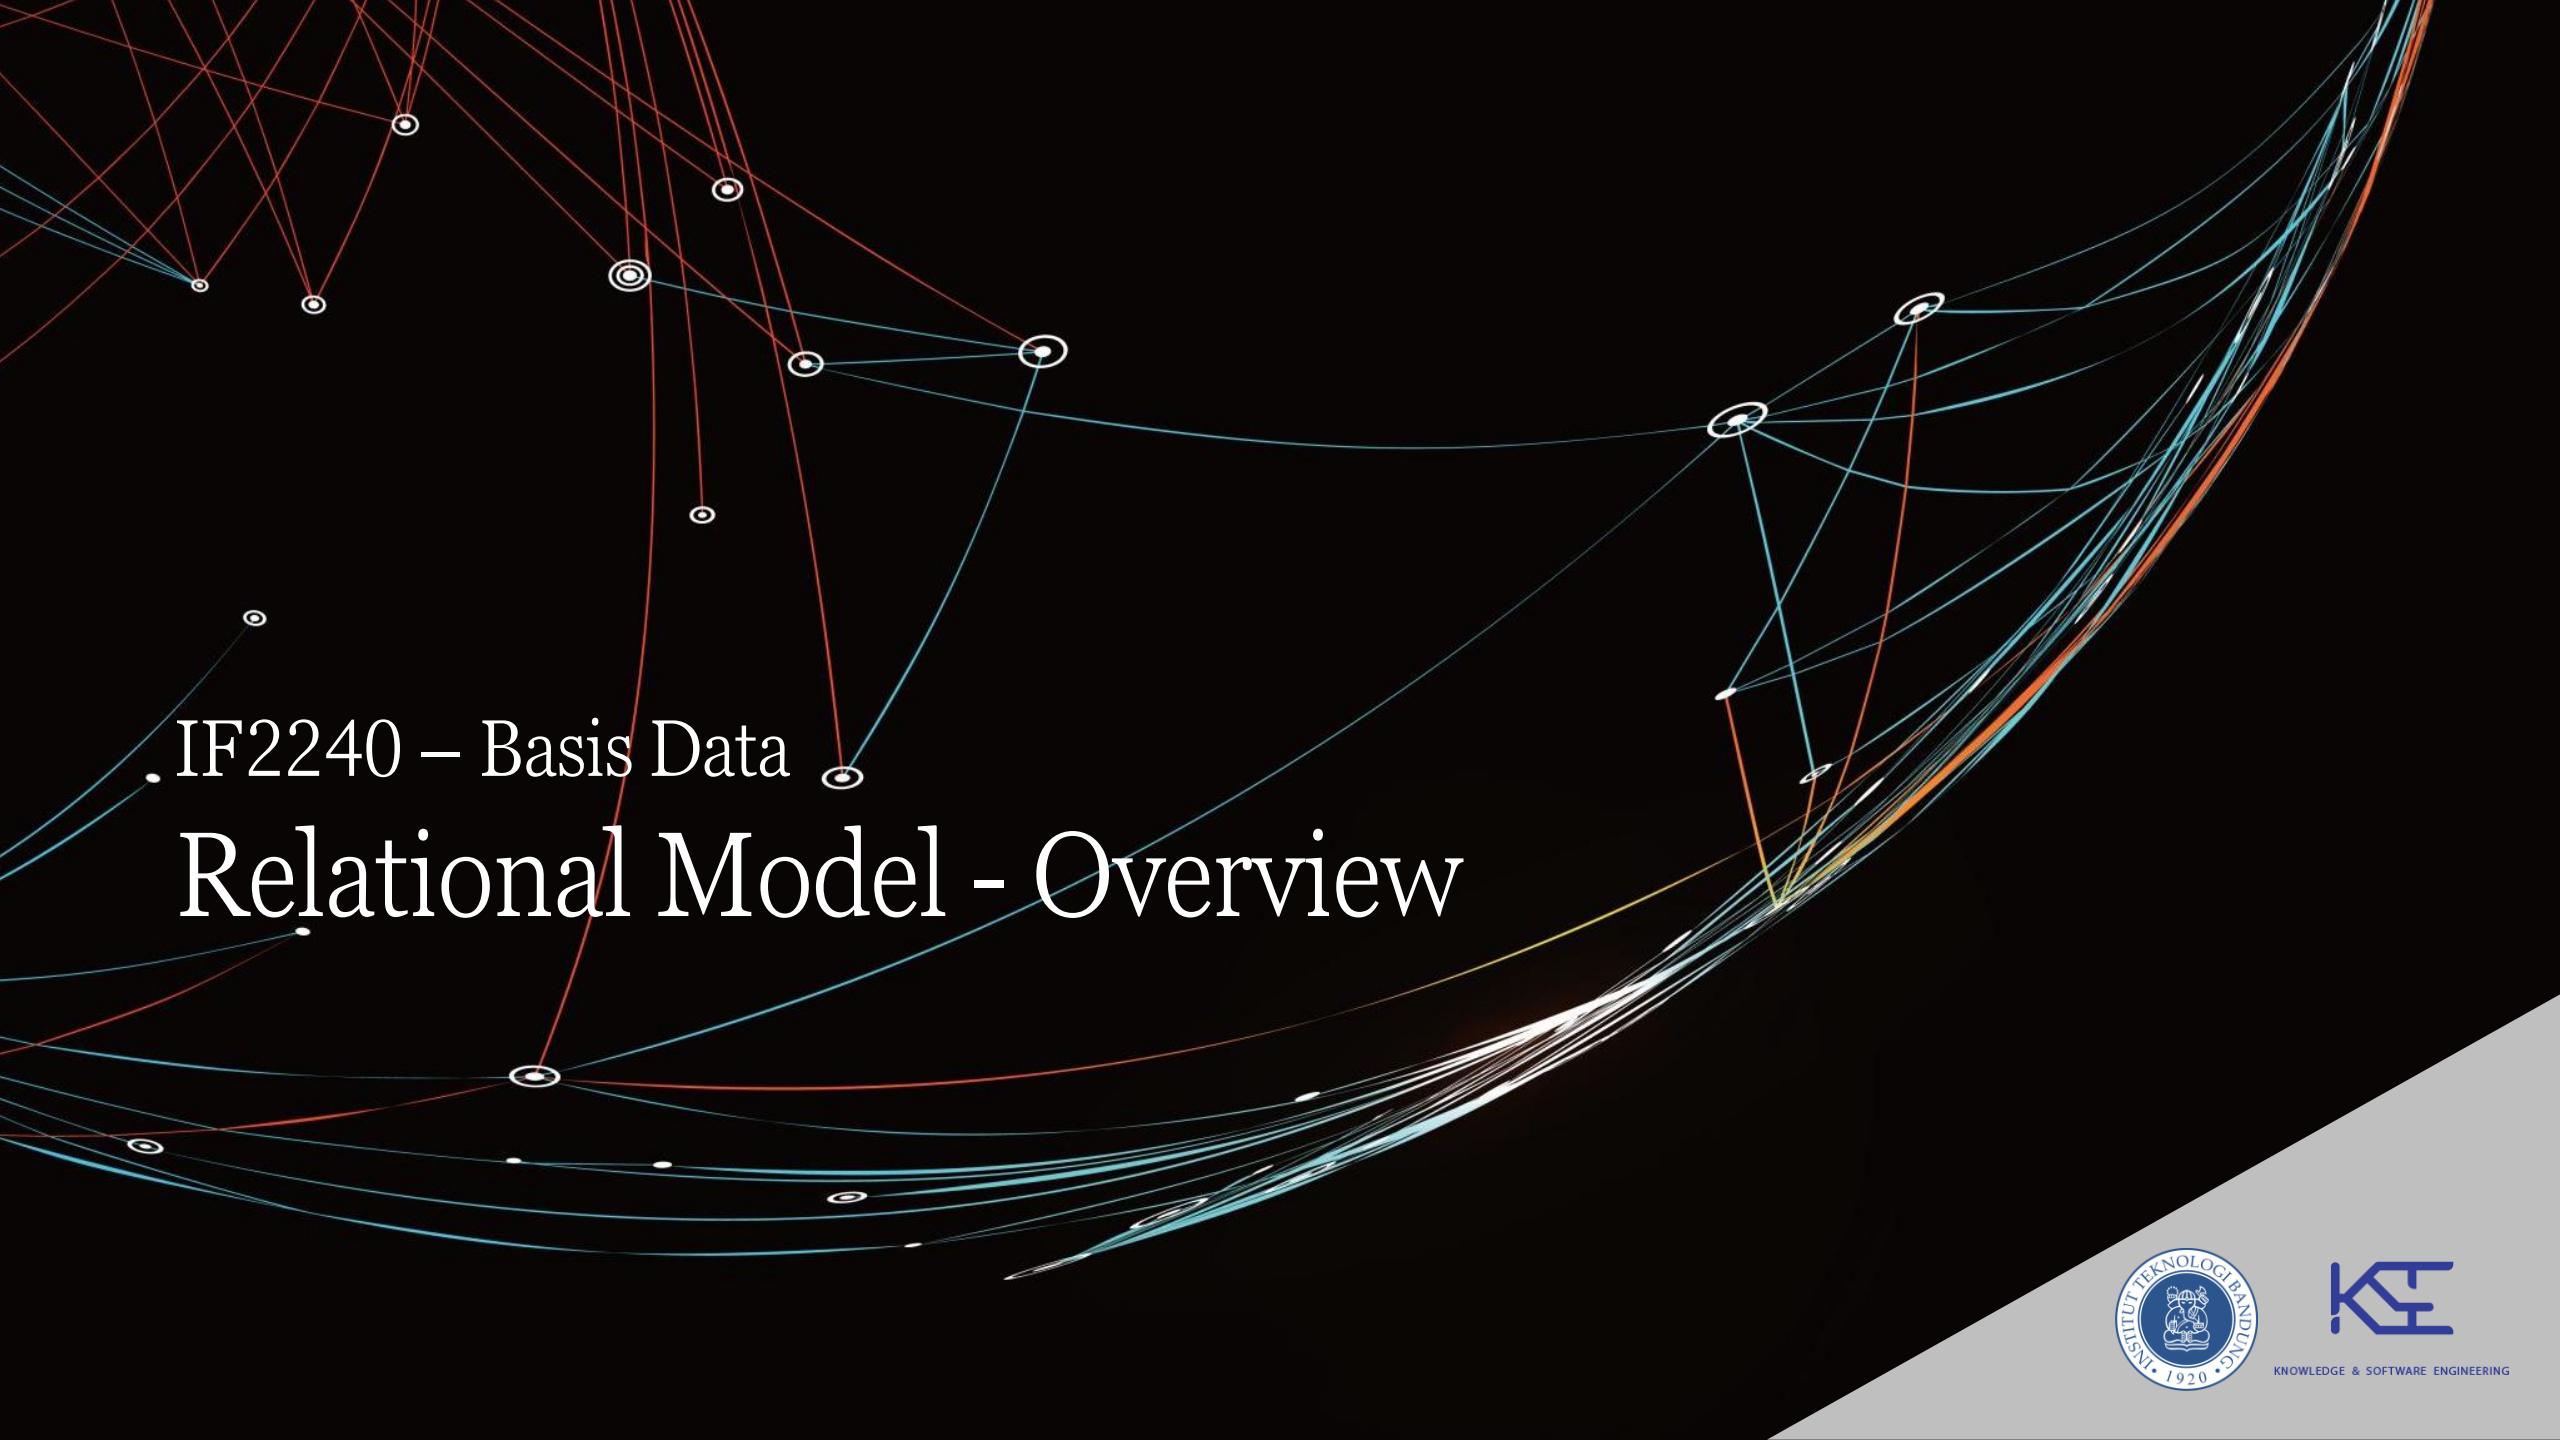

```
type customer = record
    customer-name: string;
    customer-street: string;
    customer-city: string;
end;
```

```
type account = record
    account-number: integer;
    balance: integer;
end;
```

Network Model (2/2)

- Graph like structure
 - Child may have multiple parent
- A data-structure diagram consists of two basic components:
 - Boxes, which correspond to record types
 - Lines, which correspond to links
- Specifies the overall logical structure of the database

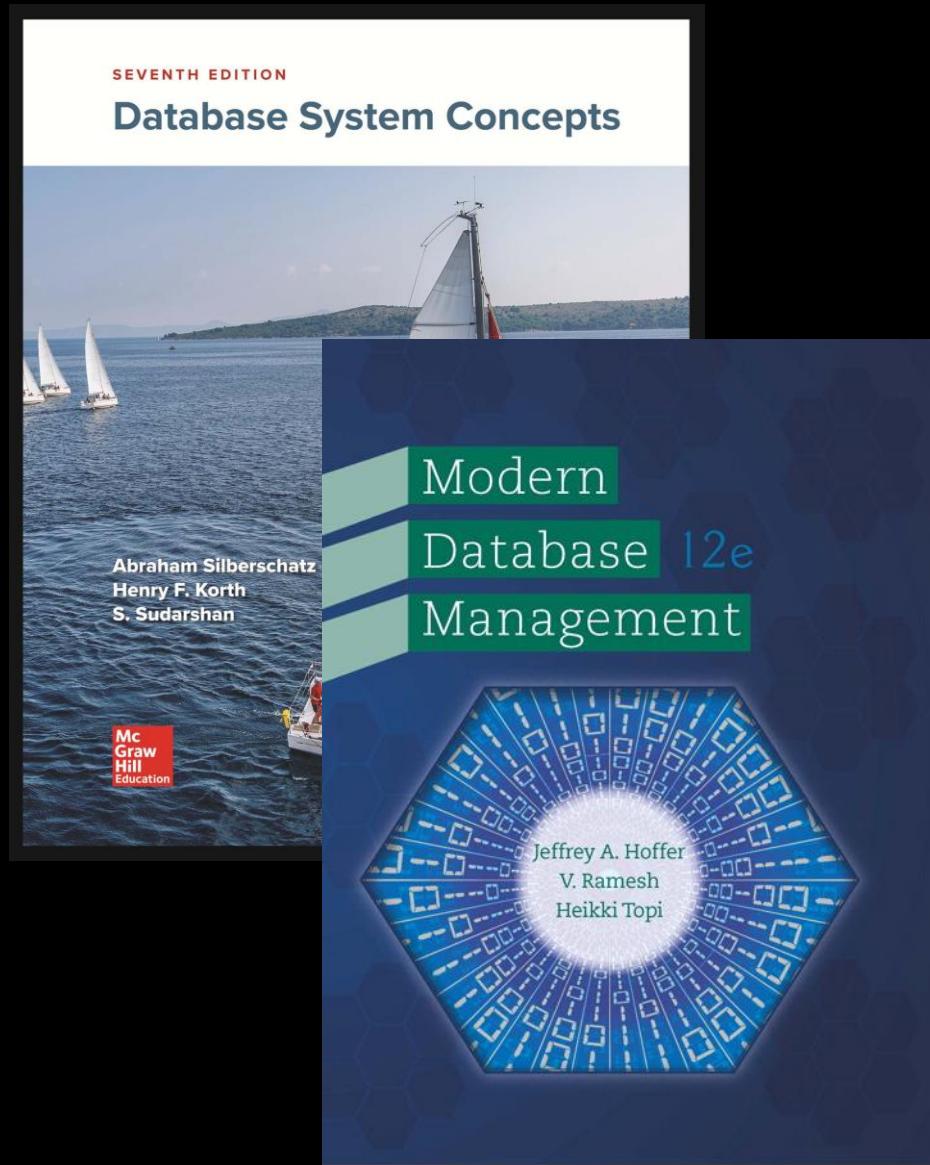

The background of the slide features a complex, abstract network graph. It consists of numerous small, semi-transparent nodes represented by small circles with a dot inside, and a dense web of thin, curved lines in various colors (red, blue, green, yellow) connecting them. Some nodes have multiple outgoing connections, while others have none, creating a organic, interconnected pattern.

IF2240 – Basis Data Relational Model - Overview

KNOWLEDGE & SOFTWARE ENGINEERING

References

Abraham Silberschatz, Henry F. Korth, S. Sudarshan :
“Database System Concepts”, 7th Edition

- Chapter 2: Introduction to the Relational Model

Jeffrey A. Hoffer, Mary B. Prescott, Heikki Topi : “Modern Database Management”, 12th Edition

- Chapter 4: Logical Database Design and the Relational Model

Relational Model Concept

- A Relation is a mathematical concept based on the **ideas of sets**
- The model was first proposed by Dr. E.F. Codd of IBM Research in 1970 in the following paper:
 - "A Relational Model for Large Shared Data Banks," Communications of the ACM, June 1970
- The above paper caused a major revolution in the field of database management and earned Dr. Codd the coveted ACM Turing Award
- Why study this? **Most widely used model**
 - Today, RDBMSs have become the dominant technology for database management, and there are literally hundreds of RDBMS products for computers ranging from smartphones and personal computers to mainframes

Relation

- Definition: A relation is a named, two-dimensional table of data
- Table consists of rows (records) and columns (attribute or field)
- Requirements for a table to qualify as a relation:
 - -It must have a unique name
 - -Every attribute value must be atomic (not multivalued, not composite)
 - -Every row must be unique (can't have two rows with exactly the same values for all their fields)
 - -Attributes (columns) in tables must have unique names
 - -The order of the columns may be unordered
 - -The order of the rows may be unordered

NOTE: all *relations* are in **1st Normal form**

tuples
(or rows)

Example : Relation Instructor

attributes
(or columns)

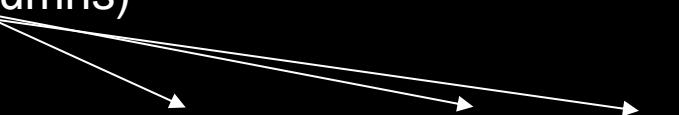

ID	name	dept_name	salary
10101	Srinivasan	Comp. Sci.	65000
12121	Wu	Finance	90000
15151	Mozart	Music	40000
22222	Einstein	Physics	95000
32343	El Said	History	60000
33456	Gold	Physics	87000
45565	Katz	Comp. Sci.	75000
58583	Califieri	History	62000
76543	Singh	Finance	80000
76766	Crick	Biology	72000
83821	Brandt	Comp. Sci.	92000
98345	Kim	Elec. Eng.	80000

Attributes

- Each attribute of a relation has a name
- The set of allowed values for each attribute is called the **domain** of the attribute
- Attribute values are (normally) required to be **atomic**; that is, indivisible
 - E.g. the value of an attribute can be an account number, but cannot be a set of account numbers
- The special value *null* is a member of every domain
- The null value causes complications in the definition of many operations
 - We shall ignore the effect of null values in our main presentation and consider their effect later
- Meanings for NULL values
 - Value unknown
 - Value exists but is not available
 - Attribute does not apply to this tuple (also known as value undefined)
- IMPORTANT: **NULL ≠ NULL**

attributes
(or columns)

ID	name	dept_name	salary
----	------	-----------	--------

Relation Schema & Instance

- A_1, A_2, \dots, A_n are *attributes*
- $R = (A_1, A_2, \dots, A_n)$ is a *relation schema*

Example:

instructor = (*ID*, *name*, *dept_name*, *salary*)

- The current values a relation are specified by a table
- An element t of relation r is called a *tuple* and is represented by a *row* in a table

Database Schema

Database schema -- is the logical structure of the database.

Database instance -- is a snapshot of the data in the database at a given instant in time.

Example:

- schema: *instructor* (*ID*, *name*, *dept_name*, *salary*)
- Instance:

<i>ID</i>	<i>name</i>	<i>dept_name</i>	<i>salary</i>
22222	Einstein	Physics	95000
12121	Wu	Finance	90000
32343	El Said	History	60000
45565	Katz	Comp. Sci.	75000
98345	Kim	Elec. Eng.	80000
76766	Crick	Biology	72000
10101	Srinivasan	Comp. Sci.	65000
58583	Califieri	History	62000
83821	Brandt	Comp. Sci.	92000
15151	Mozart	Music	40000
33456	Gold	Physics	87000
76543	Singh	Finance	80000

Why Split Information Across Relations?

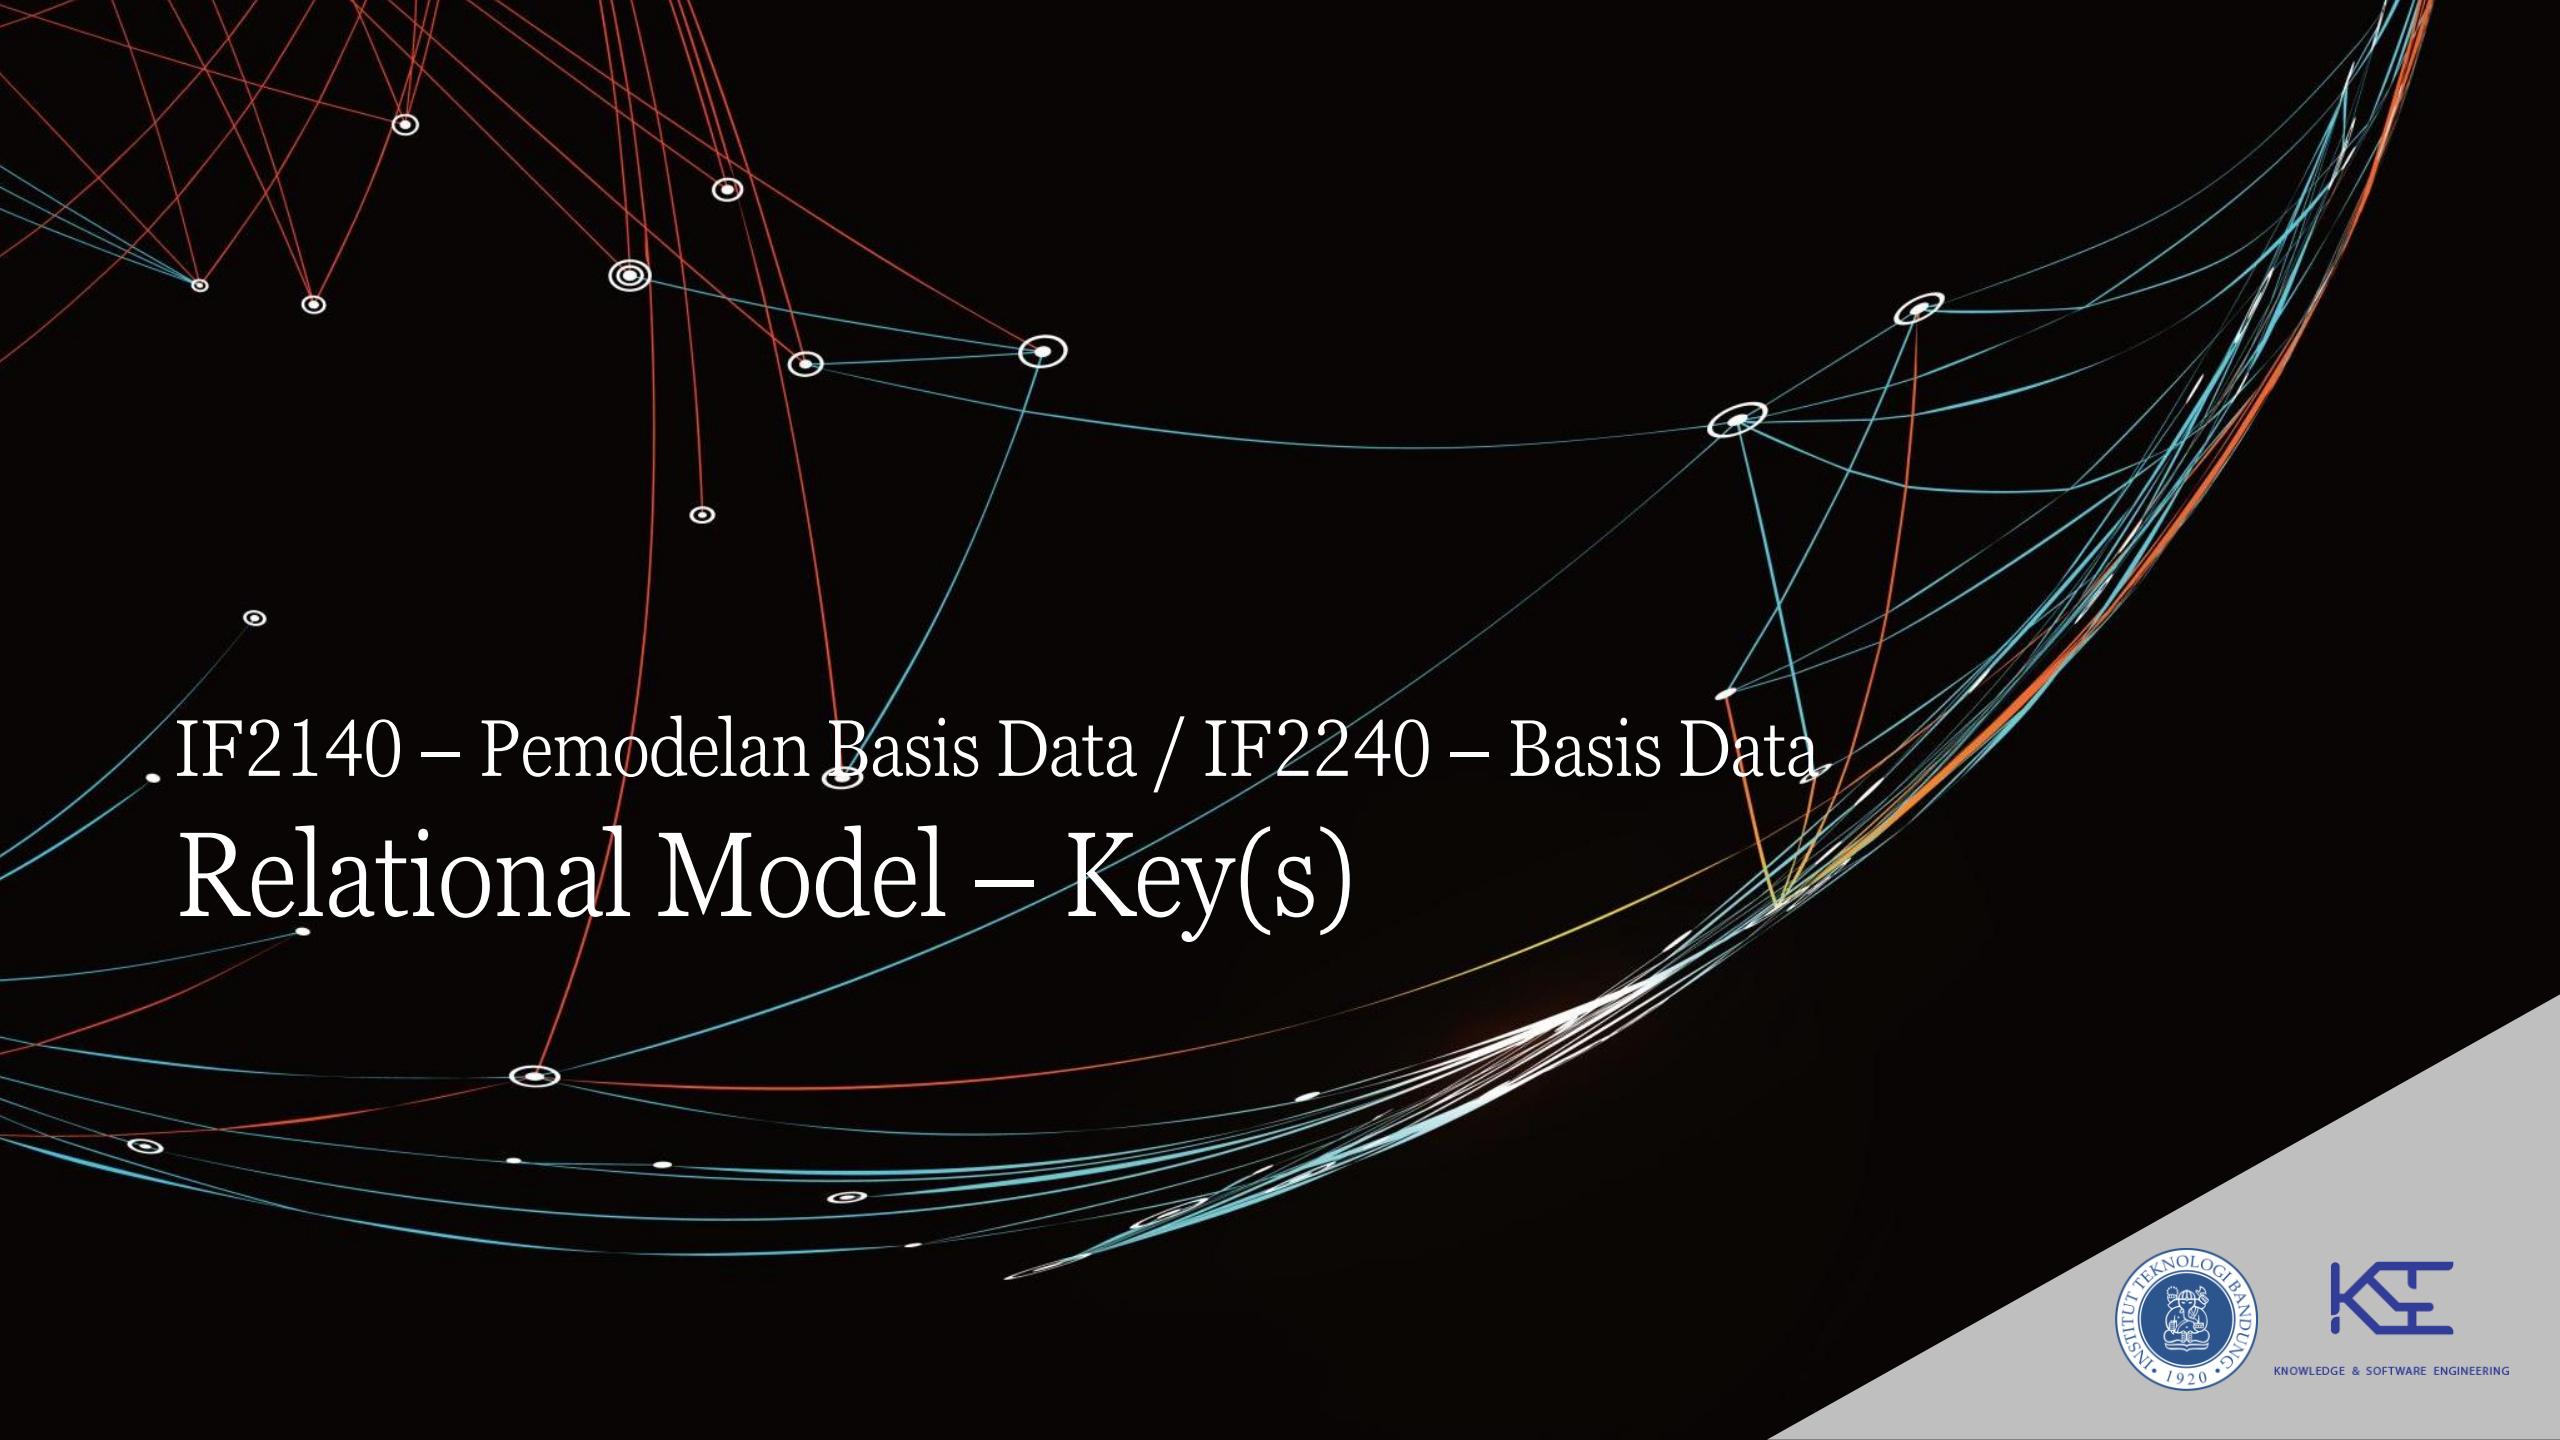

Storing all information as a single relation such as
bank(account_number, balance, customer_name, ..)
results in :

- repetition of information
 - e.g., if two customers own an account (What gets repeated?)
- the need for null values
 - e.g., to represent a customer without an account

Normalization theory (we'll come back later) deals with how to design relational schemas

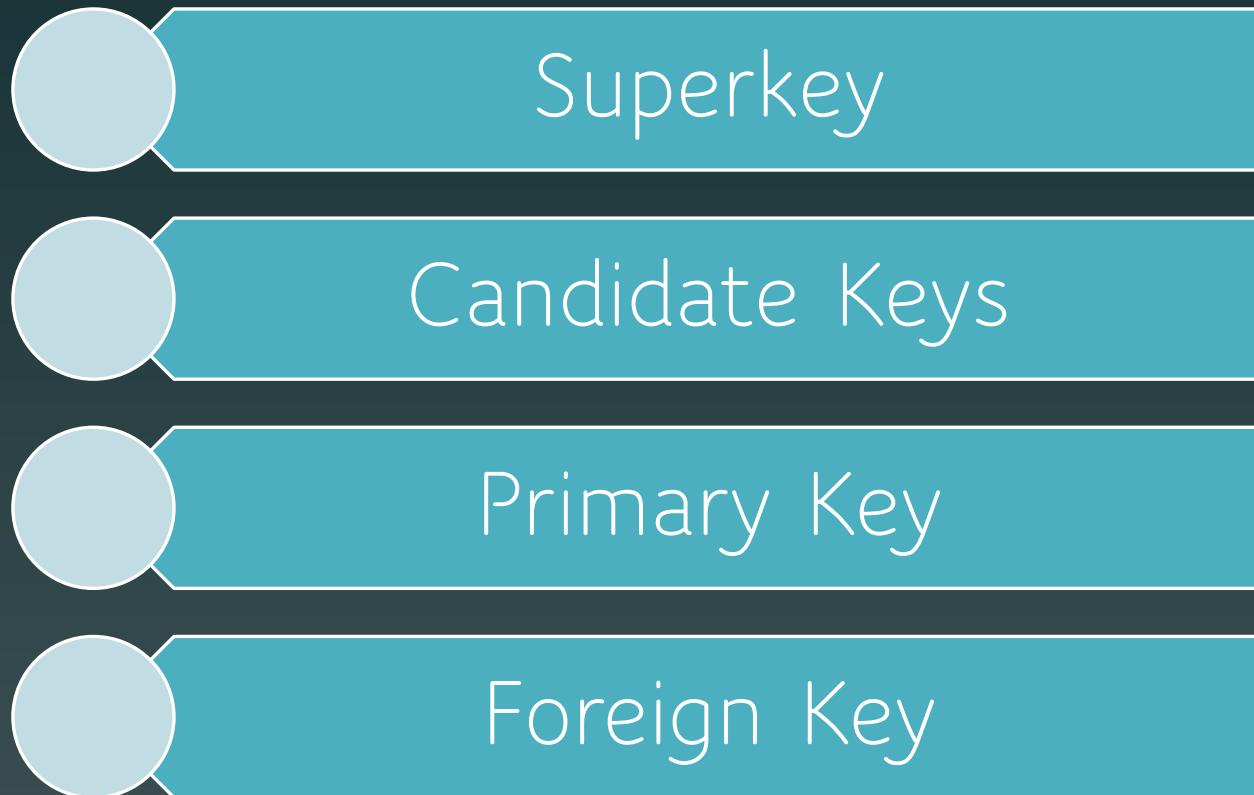

KNOWLEDGE & SOFTWARE ENGINEERING

IF2140 – Pemodelan Basis Data / IF2240 – Basis Data Relational Model – Key(s)

Keys

Superkeys

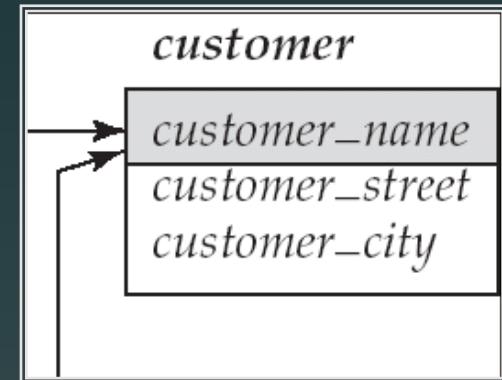

Let $K \subseteq R$

K is a **superkey** of R if values for K are sufficient to identify a unique tuple of each possible relation $r(R)$

- by “possible r ” we mean a relation r that could exist in the enterprise we are modeling.
- Example: $\{customer_name, customer_street\}$ and $\{customer_name\}$

are both superkeys of *Customer*, if no two customers can possibly have the same name

- In real life, an attribute such as $customer_id$ would be used instead of $customer_name$ to uniquely identify customers, but we omit it to keep our examples small, and instead assume customer names are unique.

Candidate and Primary Key

K is a **candidate key** if K is minimal

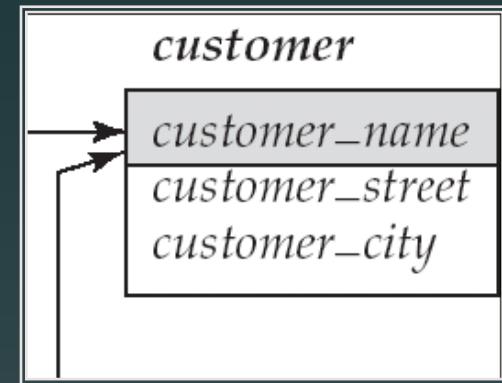

Example: $\{customer_name\}$ is a candidate key for *Customer*, since it is a superkey and no subset of it is a superkey.

Primary key: a candidate key chosen as the principal means of identifying tuples within a relation

- Should choose an attribute whose value never, or very rarely, changes.
- E.g. email address is unique, but may change

Keys can be **simple** (a single field) or **composite** (more than one field)

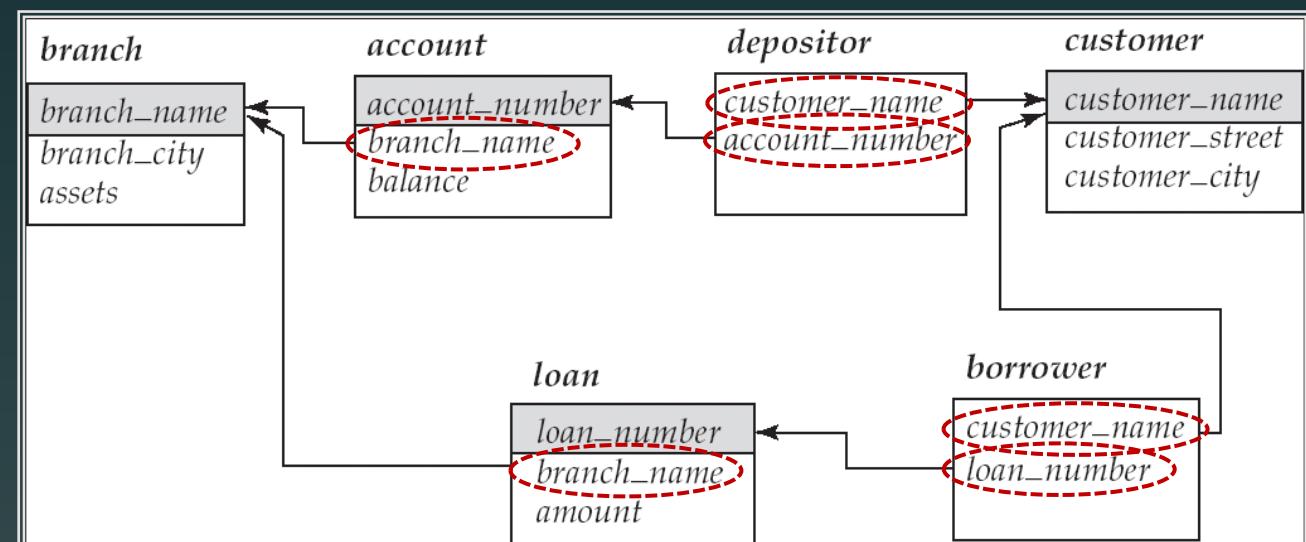

Keys usually are used as indexes to speed up the response to user queries

Foreign Keys

A relation schema may have an attribute that corresponds to the primary key of another relation. The attribute is called a **foreign key**.

- E.g. *customer_name* and *account_number* attributes of *depositor* are foreign keys to *customer* and *account* respectively.
- Only values occurring in the primary key attribute of the **referenced relation** may occur in the foreign key attribute of the **referencing relation**.

Foreign Keys

Primary Keys & Foreign Keys (Example)

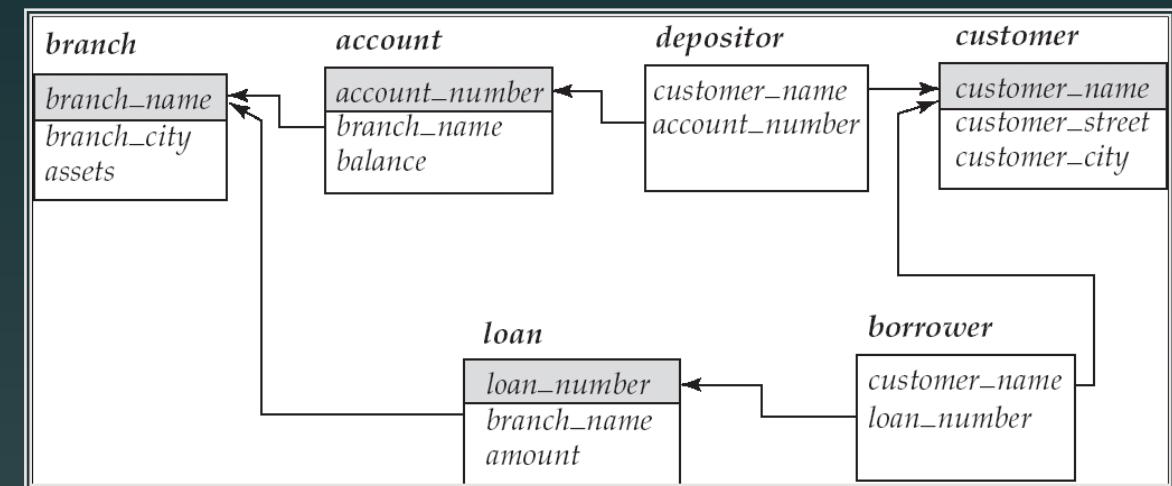

```
branch = (branch_name, branch_city, assets)
account = (account_number, branch_name, balance)
customer = (customer_name, customer_street, customer_city)
loan = (loan_number, branch_name, amount)
depositor = (customer_name, account_number)
borrower = (customer_name, loan_number)
```

FK's:

- account(branch_name) → branch(branch_name)
- loan(branch_name) → branch(branch_name)
- depositor(customer_name) → customer(customer_name)
- depositor(account_number) → account(account_number)
- borrower(customer_name) → customer(customer_name)
- borrower(loan_number) → loan(loan_number)

Note:

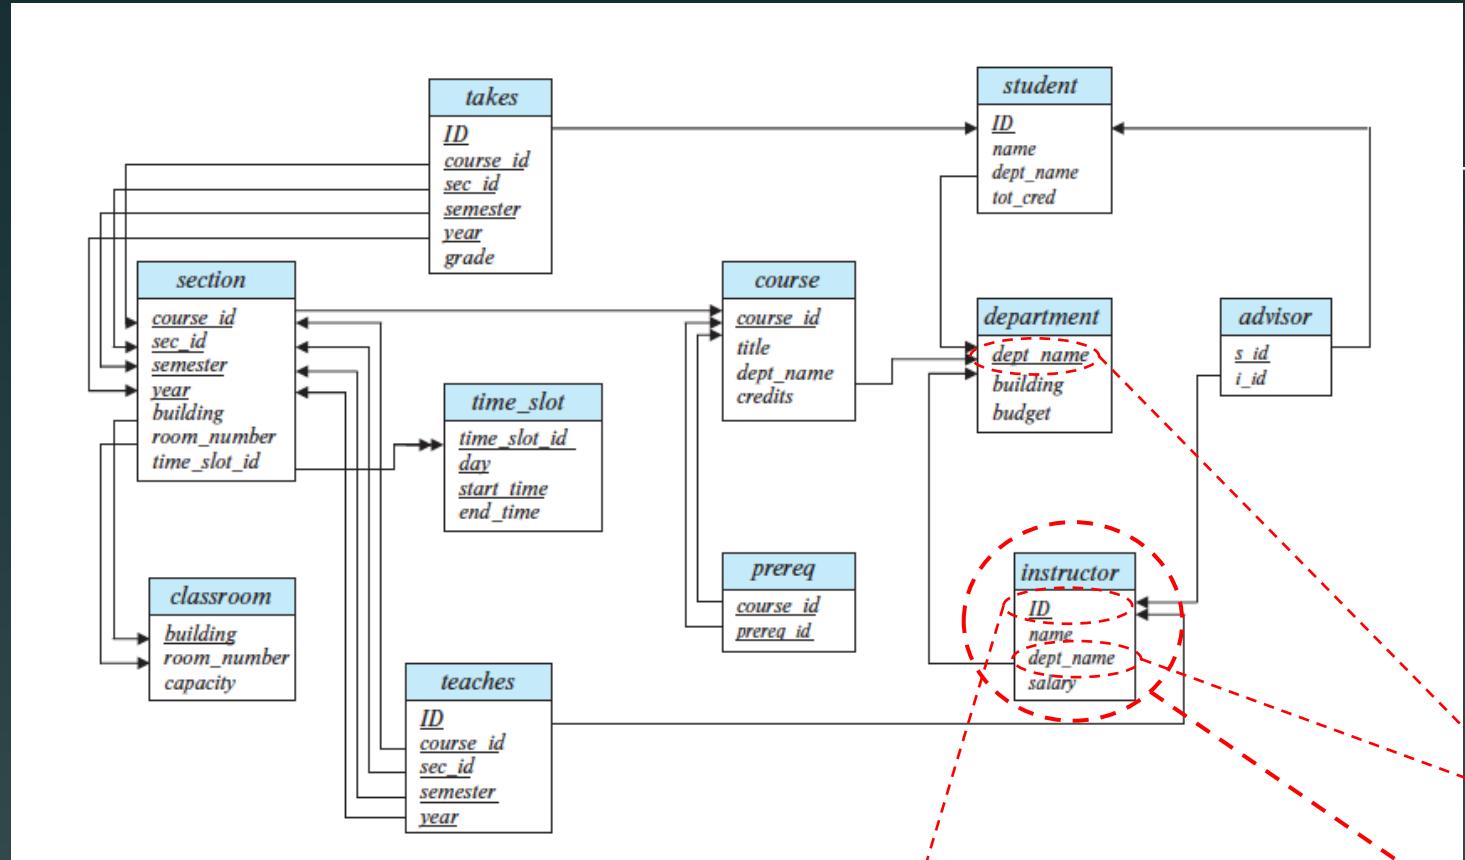

underlined : primary key

- IF2140 – Pemodelan Basis Data / IF2240 – Basis Data

Relational Model – Schema Diagram & Integrity Constraint

Schema Diagrams

Relation appears as box
Name at the top in the blue,
attributes listed inside the box

Foreign-key constraints appear as arrows
from the foreign-key attributes of the
referencing relation to the primary key of the
referenced relation

Integrity Constraint

Domain Constraints

- All of the values that appear in a column of a relation must be from the same domain.

Entity Integrity

- The entity integrity rule is designed to ensure that every relation has a primary key and that the data values for that primary key are all valid.

Referential Integrity

- Rule that maintains consistency among the rows of two relations

Domain Constraint

A domain definition usually consists of the following components: domain name, meaning, data type, size (or length), and allowable values or allowable range (if applicable).

TABLE 4-1 Domain Definitions for INVOICE Attributes

Attribute	Domain Name	Description	Domain
CustomerID	Customer IDs	Set of all possible customer IDs	character: size 5
CustomerName	Customer Names	Set of all possible customer names	character: size 25

OrderID	Order IDs	Set of all possible order IDs	character: size 5
OrderDate	Order Dates	Set of all possible order dates	date: format mm/dd/yy
ProductID	Product IDs	Set of all possible product IDs	character: size 5
ProductDescription	Product Descriptions	Set of all possible product descriptions	character: size 25
ProductFinish	Product Finishes	Set of all possible product finishes	character: size 15
ProductStandardPrice	Unit Prices	Set of all possible unit prices	monetary: 6 digits
ProductLineID	Product Line IDs	Set of all possible product line IDs	integer: 3 digits
OrderedQuantity	Quantities	Set of all possible ordered quantities	integer: 3 digits

Entity Integrity

A rule that states that no primary key attribute (or component of a primary key attribute) may be null.

If we choose this one as a primary key, so there's no null CustomerID

TABLE 4-1 Domain Definitions for INVOICE Attributes

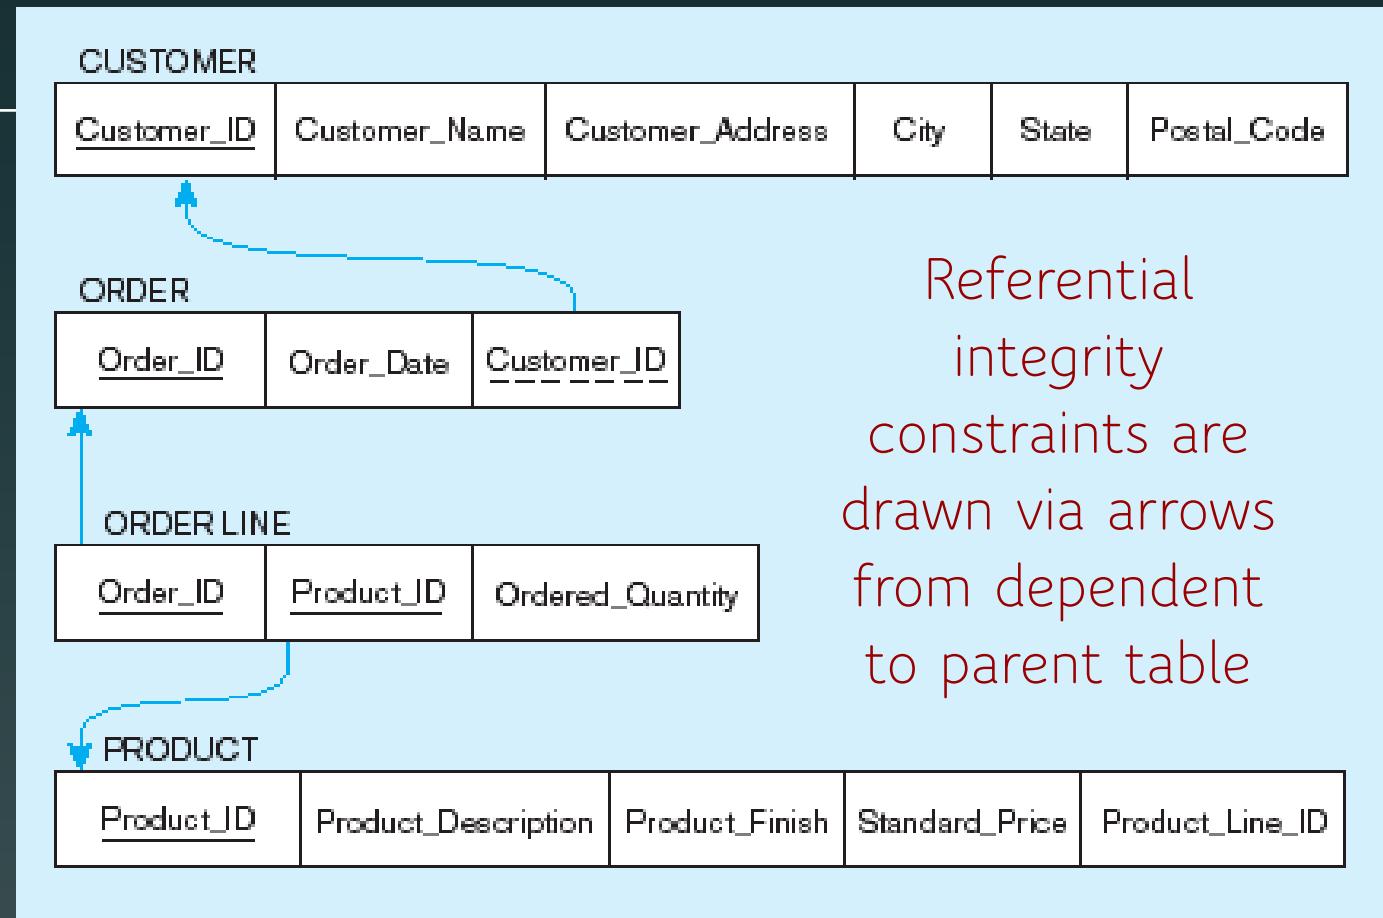

Attribute	Domain Name	Description	Domain
CustomerID	Customer IDs	Set of all possible customer IDs	character: size 5
CustomerName	Customer Names	Set of all possible customer names	character: size 25
CustomerAddress	Customer Addresses	Set of all possible customer addresses	character: size 30
CustomerCity	Cities	Set of all possible cities	character: size 20
CustomerState	States	Set of all possible states	character: size 2
CustomerPostalCode	Postal Codes	Set of all possible postal zip codes	character: size 10
OrderID	Order IDs	Set of all possible order IDs	character: size 5
OrderDate	Order Dates	Set of all possible order dates	date: format mm/dd/yy
ProductID	Product IDs	Set of all possible product IDs	character: size 5
ProductDescription	Product Descriptions	Set of all possible product descriptions	character: size 25
ProductFinish	Product Finishes	Set of all possible product finishes	character: size 15
ProductStandardPrice	Unit Prices	Set of all possible unit prices	monetary: 6 digits
ProductLineID	Product Line IDs	Set of all possible product line IDs	integer: 3 digits
OrderedQuantity	Quantities	Set of all possible ordered quantities	integer: 3 digits

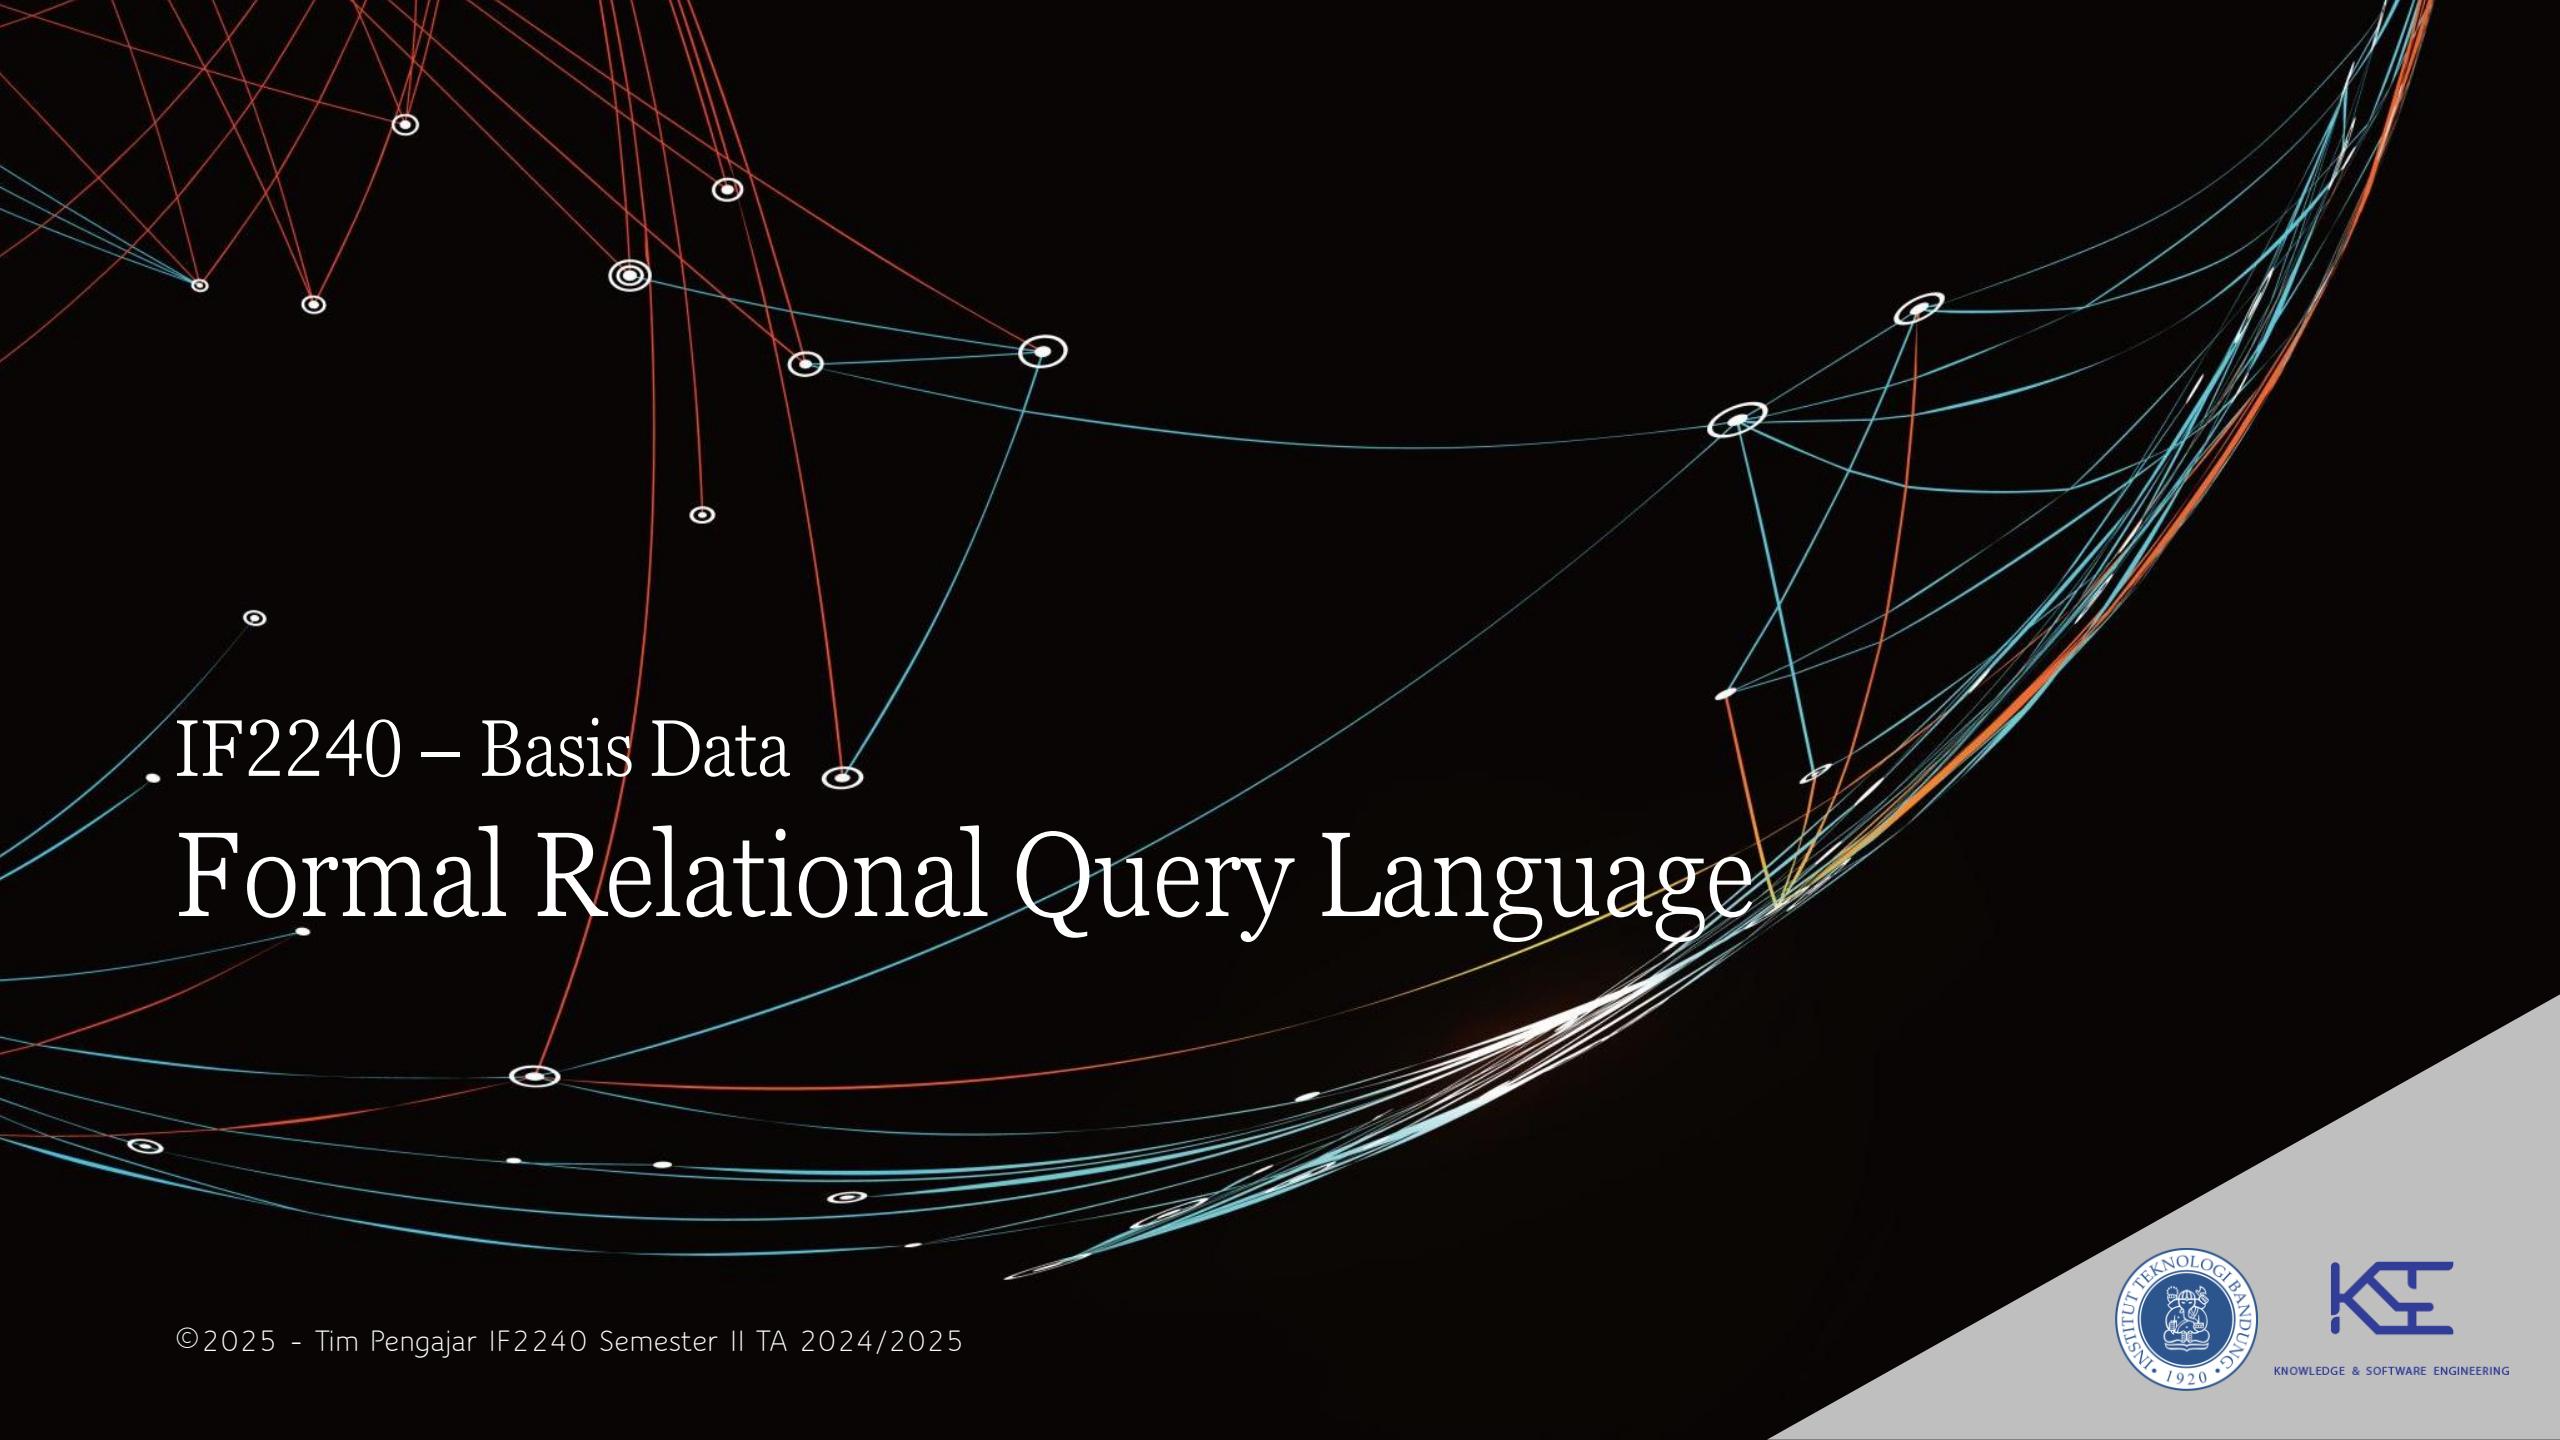

Referential Integrity

Rule states that any foreign key value MUST match a primary key value in the referenced relation (Or the foreign key can be null).

For example: Delete Rules

- **Restrict**-don't allow delete of "parent" side if related rows exist in "dependent" side
- **Cascade**-automatically delete "dependent" side rows that correspond with the "parent" side row to be deleted
- **Set-to-Null**-set the foreign key in the dependent side to null if deleting from the parent side (not allowed for weak entities)

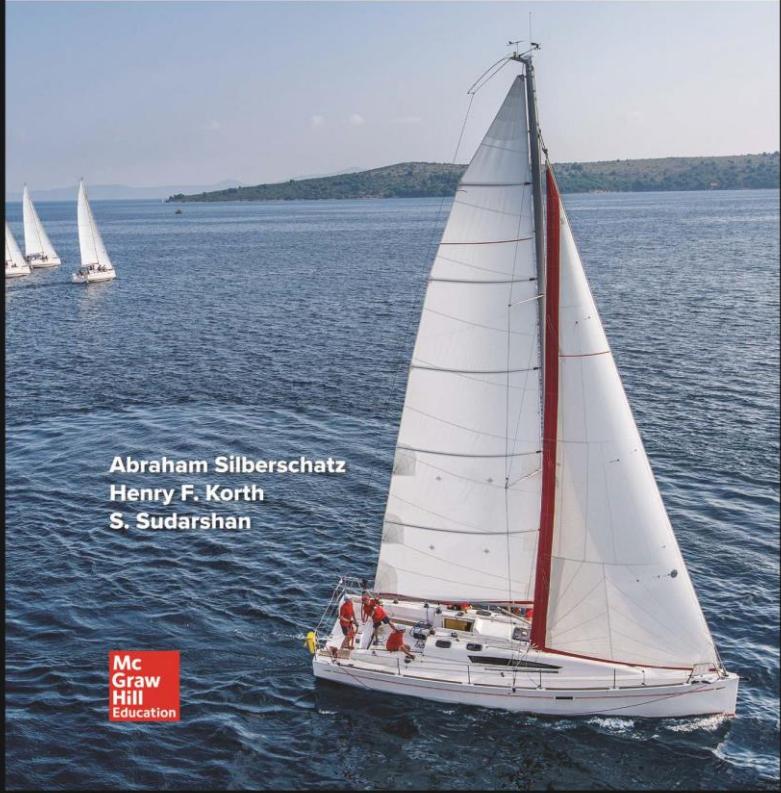

IF2240 – Basis Data Formal Relational Query Language

SEVENTH EDITION

Database System Concepts

Sumber

Silberschatz, Korth, Sudarshan: "Database System Concepts", 7th Edition

- Chapter 2: Relational Model
 - Section 2.5. Relational Query Languages
 - Section 2.6. The Relational Algebra
 - Page 47 – 58
- Chapter 27: Formal-Relational Query Languages (*online chapter*)
 - Section 27.1. The Tuple Relational Calculus
 - Section 27.2. The Domain Relational Calculus

Objective

- Demonstrate use of the relational algebra operations from mathematical set theory (union, intersection, difference, and Cartesian product) and the relational algebra operations developed specifically for relational databases (select (restrict), project, join, and division)
- Demonstrate queries in the relational algebra
- Demonstrate queries in the domain relational calculus
- Demonstrate queries in the tuple relational calculus

Query Languages

Categories of languages

1

Functional/Procedural

- Relational algebra

HOW?

2

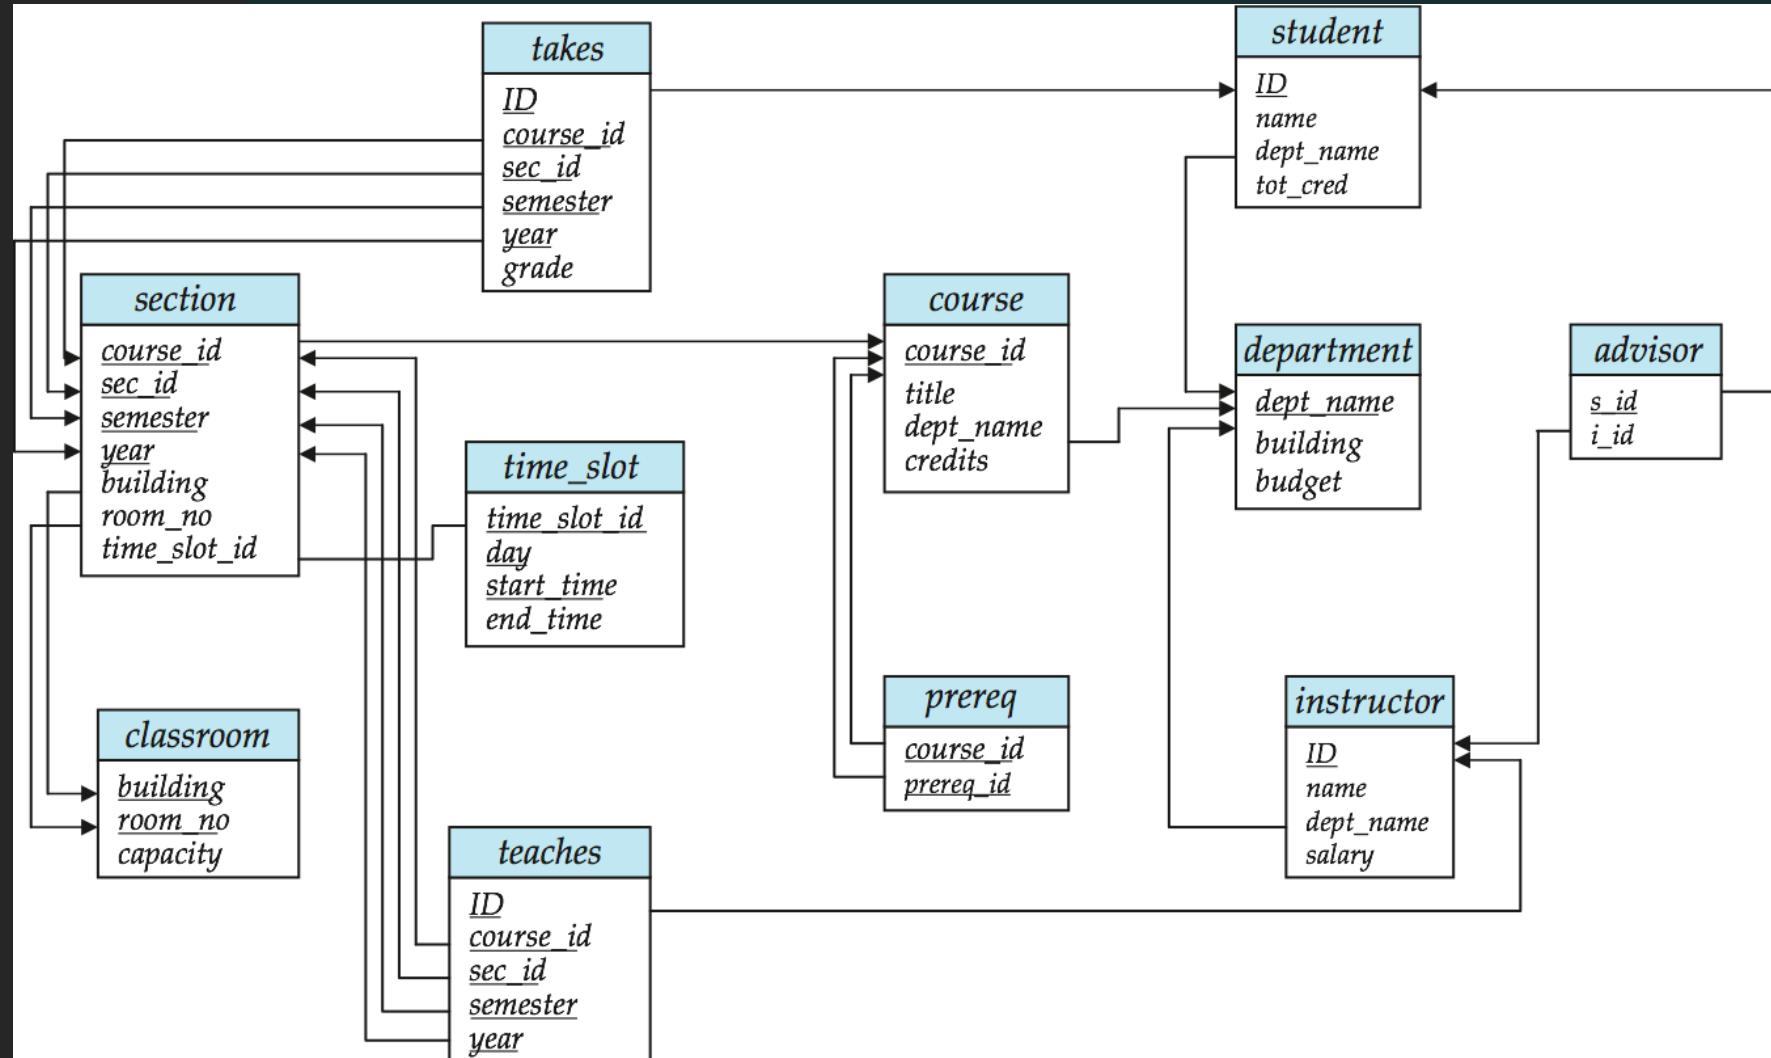

Non-procedural, or declarative

- Tuple relational calculus
- Domain relational calculus

WHAT?

Pure languages form underlying basis of query languages that people use

Schema Diagram for University Database

RELATIONAL ALGEBRA

KNOWLEDGE & SOFTWARE ENGINEERING

Relational Algebra

Procedural language

Six basic operators

- select: σ
- project: Π
- union: \cup
- set difference: $-$
- cartesian product: \times
- rename: ρ

The operators take one or two relations as inputs
and produce a new relation as a result.

- Additional Operators

- intersection
- natural join
- assignment
- outer join
- division

- Extended Operators

- generalized projection
- aggregation

Basic Operators

Select Operation

Notation

$$\sigma_p(r)$$

p = selection predicate

Defined as

$$\sigma_p(r) = \{t \mid t \in r \text{ and } p(t)\}$$

- Where p is a formula in propositional calculus: terms connected by \wedge (and), \vee (or), \neg (not)
- Term = <attribute> op <attribute> OR <constant>

Select Operation – Example 1

INSTRUCTOR (ID, NAME, DEPT_NAME, SALARY)

ID	name	dept_name	salary
22222	Einstein	Physics	95000
12121	Wu	Finance	90000
32343	El Said	History	60000
45565	Katz	Comp. Sci.	75000
98345	Kim	Elec. Eng.	80000
76766	Crick	Biology	72000
10101	Srinivasan	Comp. Sci.	65000
58583	Califieri	History	62000
83821	Brandt	Comp. Sci.	92000
15151	Mozart	Music	40000
33456	Gold	Physics	87000
76543	Singh	Finance	80000

$\sigma_{DEPT_NAME = "PHYSICS"} (INSTRUCTOR)$

ID	name	dept_name	salary
22222	Einstein	Physics	95000

RELATION R

A	B	C	D
α	α	1	7
α	β	5	7
β	β	12	3
β	β	23	10

$\sigma_{A = B \wedge D > 5}(R)$

A	B	C	D
α	α	1	7
β	β	23	10

Project Operation

Notation

$$\Pi_{A_1, A_2, \dots, A_k} (r)$$

where A_1, A_2, \dots are attribute names and r is a relation name.

Defined as

- The relation of k columns obtained by erasing the columns that are not listed
- Duplicate rows removed from result, since relations are sets

Project Operation – Example 1

INSTRUCTOR (ID, NAME, DEPT_NAME, SALARY)

ID	name	dept_name	salary
22222	Einstein	Physics	95000

β	2

Composition of Relational Operations

The result of a relational-algebra operation is a relation and therefore some of relational-algebra operations can be composed together into a **relational-algebra expression**.

Consider the query -- Find the names of all instructors in the Physics department.

$$\Pi_{name}(\sigma_{dept_name = "Physics"}(instructor))$$

KNOWLEDGE & SOFTWARE ENGINEERING

Union Operation

- Notation

$$r \cup s$$

- Defined as

$$r \cup s = \{t \mid t \in r \text{ or } t \in s\}$$

- Requirement

1. r, s must have the same *arity*

2. The attribute domains must be **compatible**

Union Operation – Example 1

RELATIONS

R

A	B
α	1
α	2
β	1

S

A	B
α	2
β	3

$R \cup S:$

A	B
α	1
α	2
β	1
β	3

Union Operation – Example 2

section
<u>course_id</u>
<u>sec_id</u>
<u>semester</u>
<u>year</u>
building
room_no
time_slot_id

Find all courses taught in the Fall 2017 semester, or in the Spring 2018 semester, or in both

$$\Pi_{course_id} (\sigma_{semester="Fall"} \wedge year=2017 (section)) \cup \\ \Pi_{course_id} (\sigma_{semester="Spring"} \wedge year=2018 (section))$$

Set Difference Operation

- Notation

$$r - s$$

- Defined as

$$r - s = \{t \mid t \in r \text{ and } t \notin s\}$$

- Requirement

Set differences must be taken between *compatible* relations

Set Difference Operation – Example 1

RELATIONS

R

A	B
α	1
α	2
β	1

S

A	B
α	2
β	3

$R - S:$

A	B
α	1
β	1

Set Difference Operation – Example 2

section
<u>course_id</u>
<u>sec_id</u>
<u>semester</u>
<u>year</u>
building
room_no
time_slot_id

Find all courses taught in the Fall 2017 semester,
but not in the Spring 2018 semester

$$\Pi_{course_id} (\sigma_{semester="Fall"} \wedge year=2017 (section)) - \\ \Pi_{course_id} (\sigma_{semester="Spring"} \wedge year=2018 (section))$$

Cartesian-Product Operation

Notation

$r \times s$

Defined as

$$r \times s = \{t \mid q \mid t \in r \text{ and } q \in s\}$$

Requirement

- Attributes of $r(R)$ and $s(S)$ are disjoint
- If attributes of $r(R)$ and $s(S)$ are not disjoint, then:
renaming OR attach its source relation

instructor.ID

Cartesian-Product Operation – Example 1

RELATIONS

R

A	B
α	1
β	2

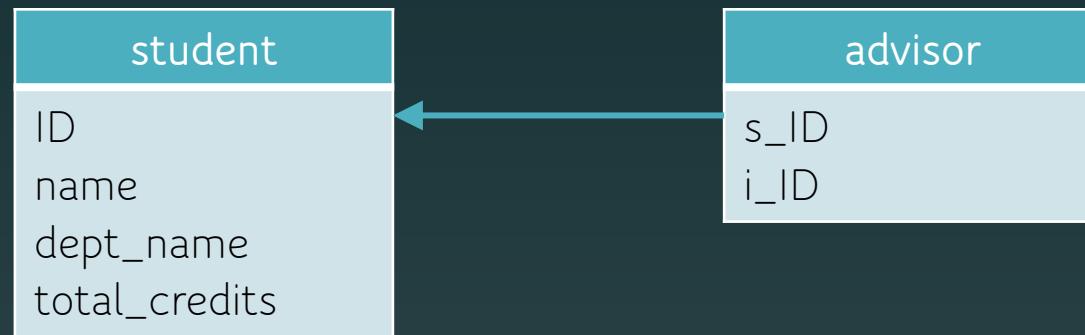

S

C	D	E
α	10	a
β	10	a
β	20	b
γ	10	b

R X S:

A	B	C	D	E
α	1	α	10	a
α	1	β	10	a
α	1	β	20	b
α	1	γ	10	b
β	2	α	10	a
β	2	β	10	a
β	2	β	20	b
β	2	γ	10	b

Cartesian-Product Operation – Example 2

Find the names of all students whose advisor's id is 22222

$$\Pi_{name} (\sigma_{i_ID=22222} (\sigma_{ID= s_ID} (student \times advisor)))$$

Rename Operation

- Usage
 - To name the results of relational-algebra expressions.
 - To refer to a relation by more than one name
- Notation (relation)

$$\rho_x(E)$$

returns the result of expression E under the name X

- Notation (attributes)

$$\rho_{x(A_1, A_2, \dots, A_n)}(E)$$

returns the result of expression E under the name X , and with the attributes renamed to A_1, A_2, \dots, A_n .

Rename Operation - Example

instructor
ID
name
dept_name
salary

Find the ID and name of those instructors who earn more than the instructor whose ID is 12121

$$\prod_{z.ID, z.name} (\sigma_{z.salary > w.salary} (\rho_z (instructor) \times (\sigma_{ID=12121} (\rho_w (instructor))))))$$

Formal Definition

A basic expression in the relational algebra consists of either one of the following:

- A relation in the database
- A constant relation

Let E_1 and E_2 be relational-algebra expressions; the following are all relational-algebra expressions:

- $E_1 \cup E_2$
- $E_1 - E_2$
- $E_1 \times E_2$
- $\sigma_P(E_1)$, P is a predicate on attributes in E_1
- $\prod_s(E_1)$, S is a list consisting of some of the attributes in E_1
- $\rho_x(E_1)$, x is the new name for the result of E_1

Example Queries

Find all instructors with salary over \$80000

Find the names of all instructors in Comp. Sci. dept with salary > 80000

Find the names of all person in the university

Example Queries

Find the title of all courses offered in Fall 2017 semester.

Find the title of all courses offered in Fall 2017 semester that do not have any prerequisites.

Example Queries

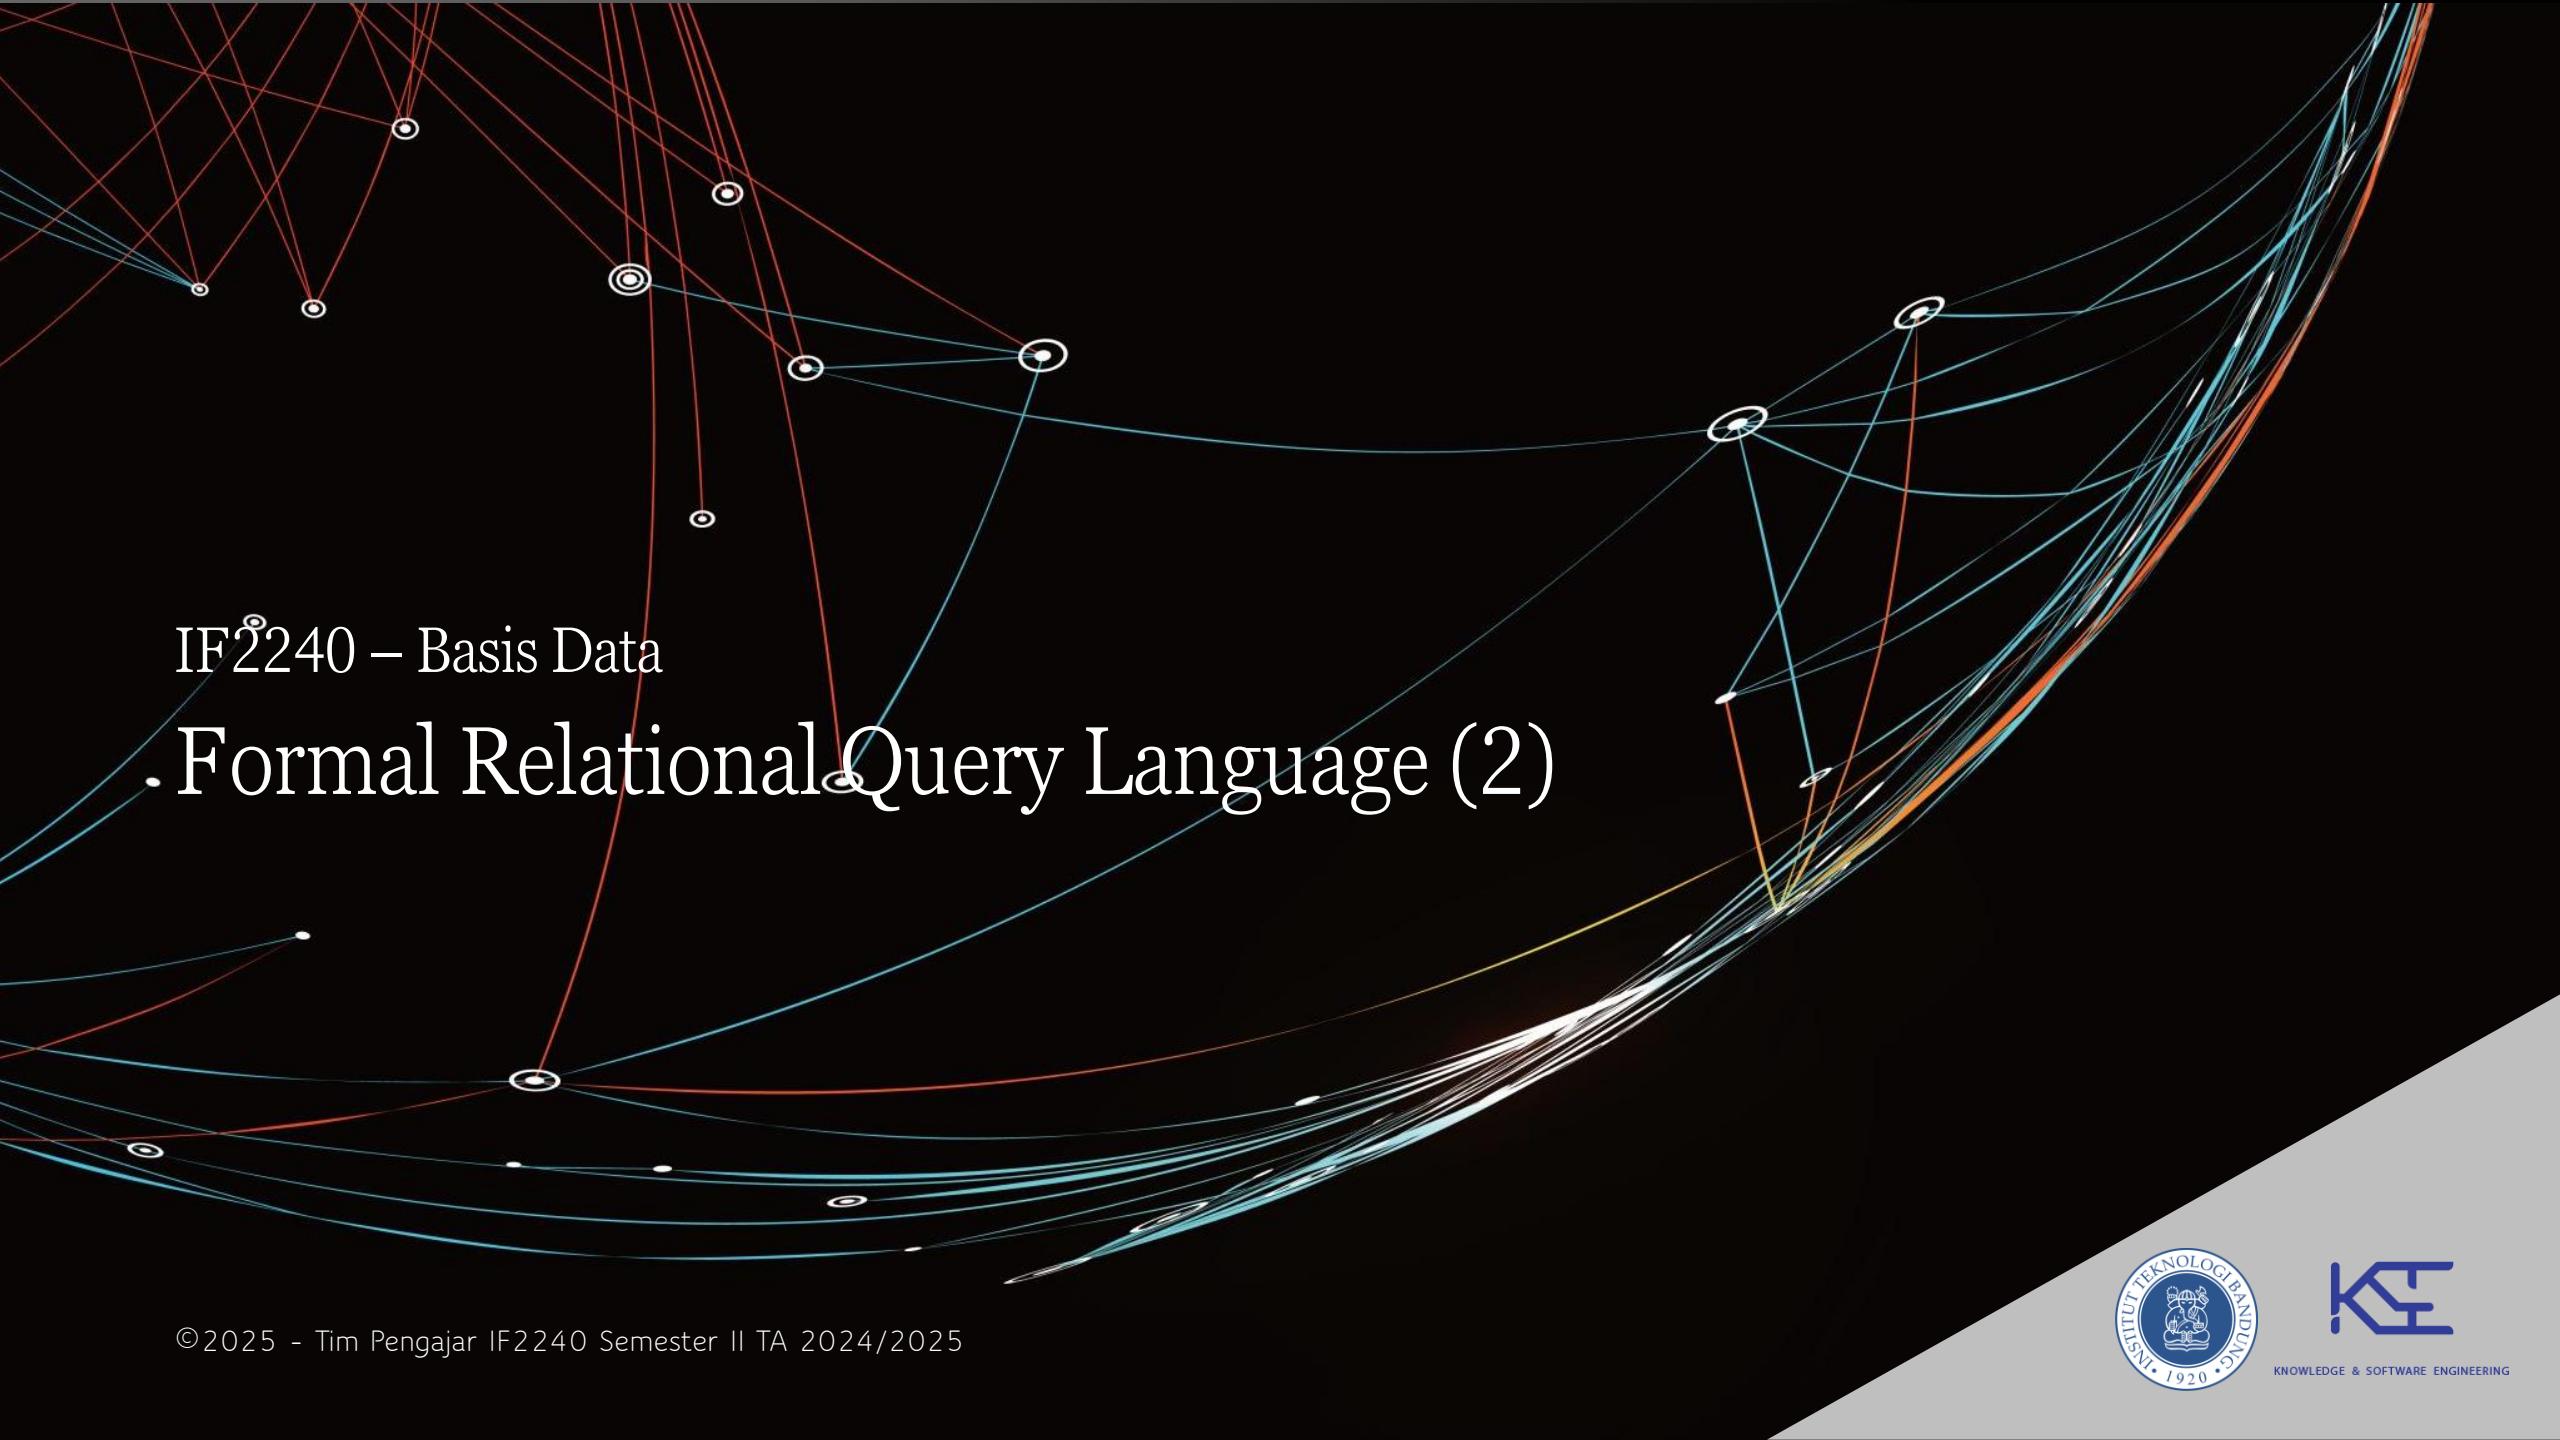

Find the names of all instructors who are located at Archway Bldg.

Example Queries

Find the names of all instructors in the Physics department, along with the *course_id* of all courses they have taught

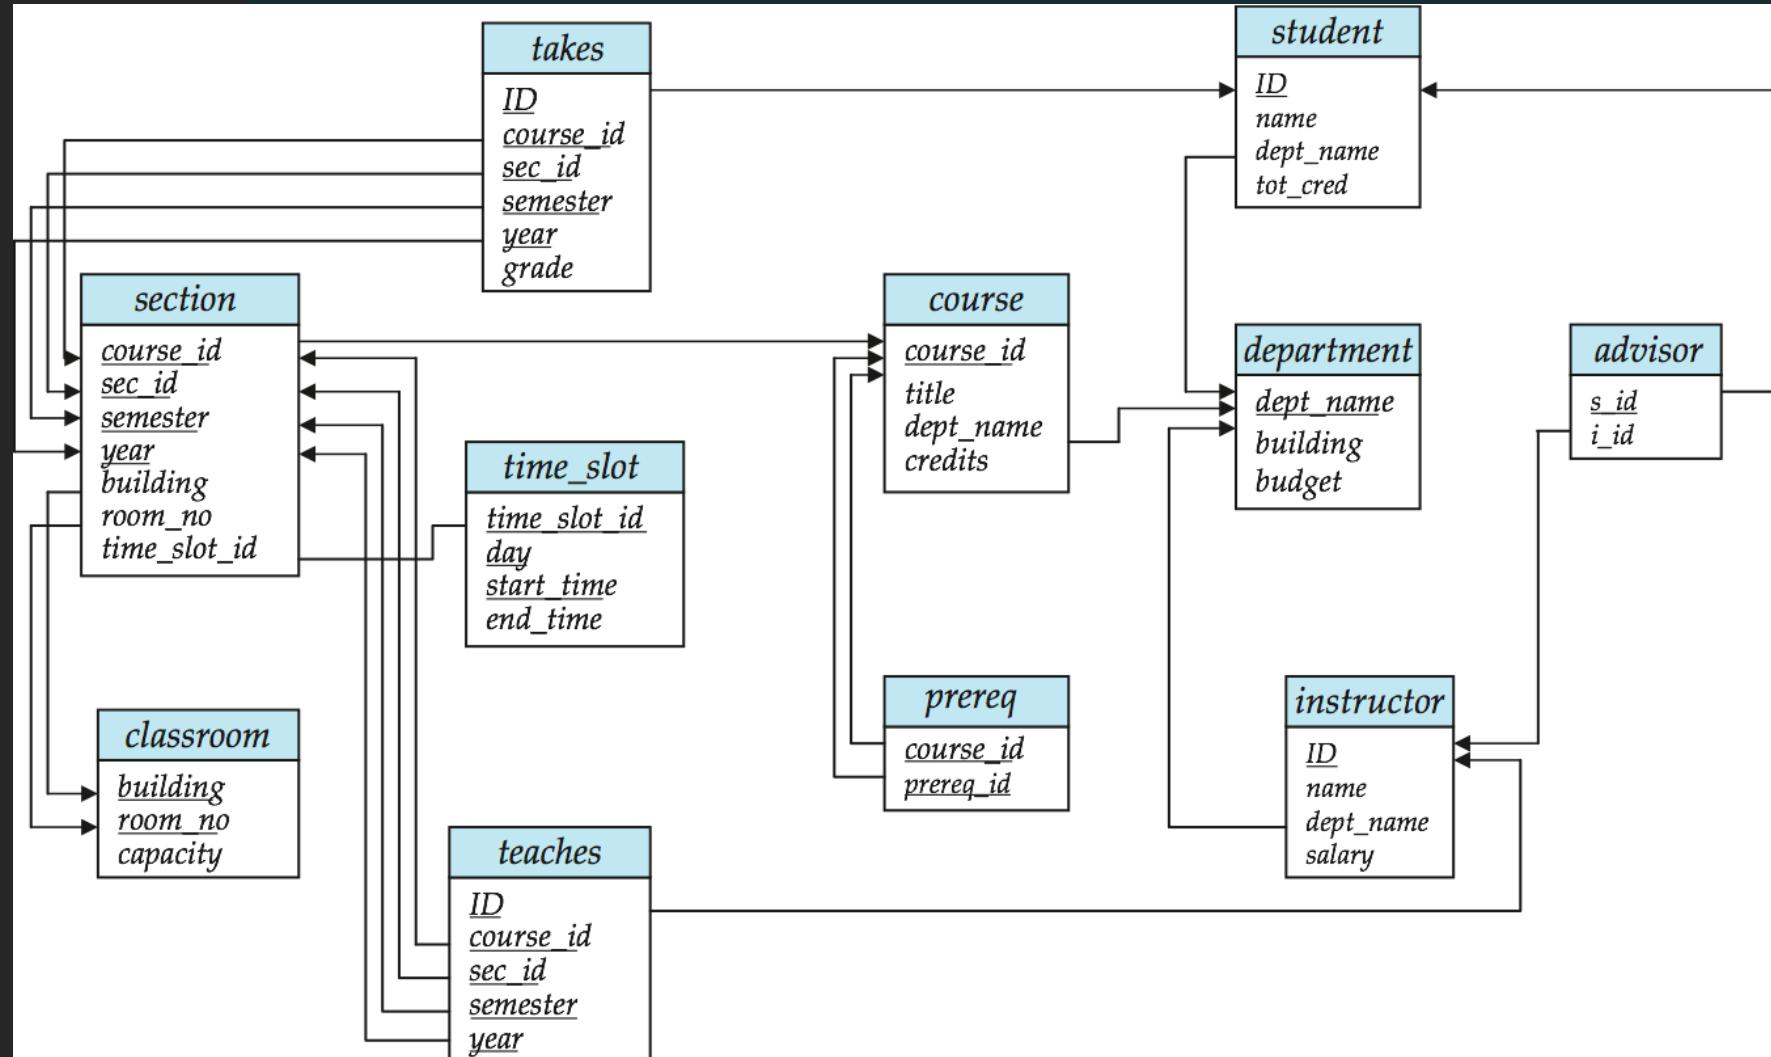

Example Query

Find the largest salary in the university

The background of the slide features a complex, abstract network graph. It consists of numerous small, glowing nodes (dots) of various colors (red, blue, green, yellow) connected by thin, curved lines of the same colors. The lines form a dense web of paths across the dark background.

IF2240 – Basis Data Formal Relational Query Language (2)

Schema Diagram for University Database

Relational Algebra

Procedural language

Six basic operators

- select: σ
- project: Π
- union: \cup
- set difference: $-$
- cartesian product: \times
- rename: ρ

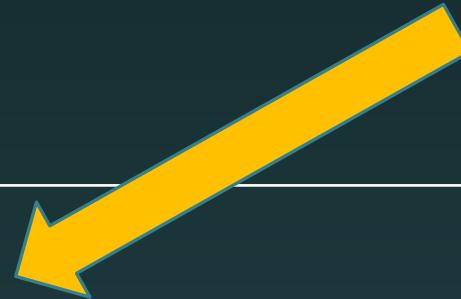

The operators take one or two relations as inputs
and produce a new relation as a result.

- Additional Operators

- Intersection: \cap
- natural join: \bowtie
- assignment: \leftarrow
- outer join: \bowtie^*
- division: \div

- Extended Operators

- generalized projection
- aggregation

Additional Operators

Additional Operations

We define additional operations that do not add any power to the relational algebra, but that simplify common queries.

- Set intersection
- Natural join
- Assignment
- Outer join
- Division

Set-Intersection Operation

Notation

$$r \cap s$$

Defined as

$$r \cap s = \{ t \mid t \in r \text{ and } t \in s \}$$

Requirement

Set intersection must be taken between *compatible* relations.

KNOWLEDGE & SOFTWARE ENGINEERING

Set-Intersection Operation – Example 1

RELATIONS

R

A	B
α	1
α	2
β	1

S

A	B
α	2
β	3

$R \cap S:$

A	B
α	2

Set-Intersection Operation

Define set-intersection by using basic operators

$$r \cap s = r - (r - s)$$

Natural-Join Operation

Notation

$$r \bowtie s$$

Defined as

- Let r and s be relations on schemas R and S respectively.
Then, $r \bowtie s$ is a relation on schema $R \cup S$ obtained as follows:
 - If t_r and t_s have the same value on each of the attributes in $R \cap S$, add a tuple t to the result (concatenation of t_r and t_s)

Natural Join Operation – Example 1

RELATIONS

R

A	B	C	D
α	1	α	a
β	2	γ	a
γ	4	β	b
α	1	γ	a
δ	2	β	b

S

B	D	E
1	a	α
3	a	β
1	a	γ
2	b	δ
3	b	ε

$R \bowtie S$

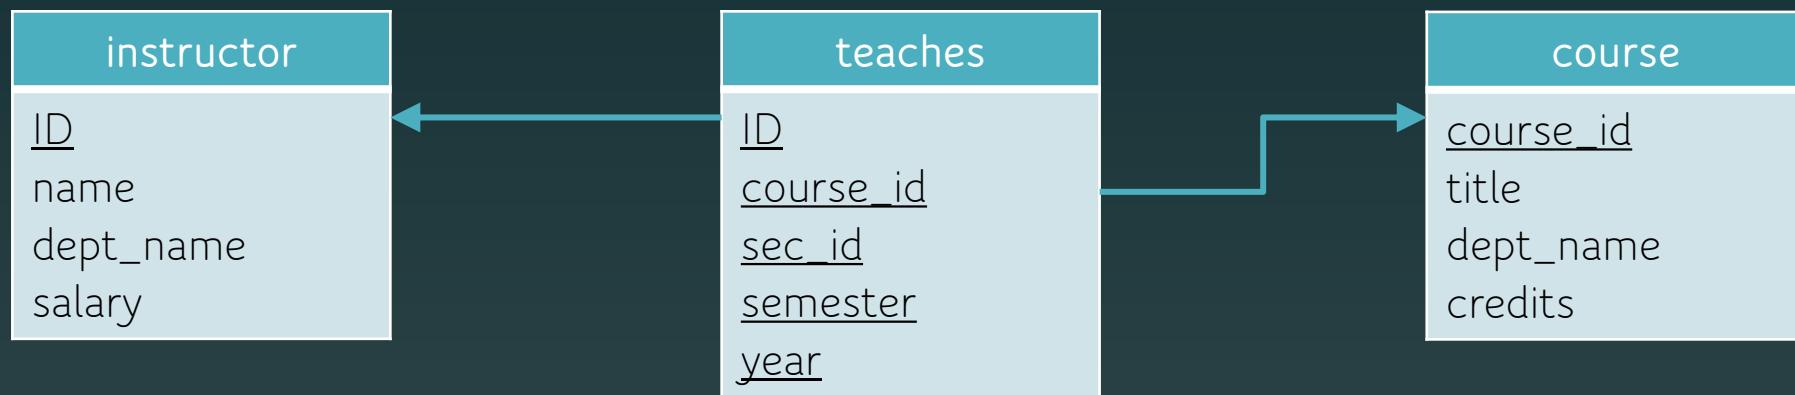

A	B	C	D	E
α	1	α	a	α
α	1	α	a	γ
α	1	γ	a	α
α	1	γ	a	γ
δ	2	β	b	δ

Note: natural join can be expressed using basic operations.

e.g. $r \bowtie s$ can be written as

$$\prod_{r.A, r.B, r.C, r.D, s.E} (\sigma_{r.B = s.B \wedge r.D = s.D} (r \times s))$$

Natural Join Operation – Example 2

Find the names of all instructors in the Comp. Sci. department together with the course titles of all the courses that the instructors teach

$$\Pi_{name, title} (\sigma_{dept_name="Comp. Sci."} (instructor \bowtie teaches \bowtie course))$$

$$\Pi_{name, title} (\sigma_{dept_name="Comp. Sci."} (instructor \bowtie teaches \bowtie \Pi_{course_id, title} (course)))$$

Natural Join and Theta Join

Natural join is associative

$(instructor \bowtie teaches) \bowtie course$ is equivalent to
 $instructor \bowtie (teaches \bowtie course)$

Natural join is commutative

$instructor \bowtie teaches$ is equivalent to
 $teaches \bowtie instructor$

The theta join operation

$$r \bowtie_{\theta} s = \sigma_{\theta}(r \times s)$$

Assignment Operation

The assignment operation (\leftarrow) provides a convenient way to express complex queries.

- Write query as a sequential program consisting of
 - a series of assignments
 - followed by an expression whose value is displayed as a result of the query.
- Assignment must always be made to a temporary relation variable.

Example: Find all instructor in the “Physics” and “Music” department.

$Physics \leftarrow \sigma_{dept_name = "Physics"}(instructor)$

$Music \leftarrow \sigma_{dept_name = "Music"}(instructor)$

$Physics \cup Music$

Outer Join

Notation:

- Left outer join: \bowtie_l
- Right outer join: \bowtie_r
- Full outer join: \bowtie_f

Defined as

- Computes the join and then adds tuples from one relation that does not match tuples in the other relation to the result of the join.

Uses *null* values

- *null* signifies that the value is unknown or does not exist
- All comparisons involving *null* are (roughly speaking) **false** by definition.

Outer Join Operation

Express outer join (e.g. $r \bowtie s$)
using basic [and join - to simplify]
operations

$$(r \bowtie s) \cup ((r - \prod_R (r \bowtie s)) \times \{(null, \dots, null)\})$$

Null Values

It is possible for tuples to have a null value, denoted by *null*, for some of their attributes

null signifies an unknown value or that a value does not exist.

The result of any arithmetic expression involving *null* is *null*.

Aggregate functions simply ignore null values (as in SQL)

For duplicate elimination and grouping, null is treated like any other value, and two nulls are assumed to be the same (as in SQL)

Null Values

Comparisons with null values return the special truth value: *unknown*

- If *false* was used instead of *unknown*, then $\text{not } (A < 5)$ would not be equivalent to $A \geq 5$

Three-valued logic using the truth value *unknown*:

- OR: $(\text{unknown or true}) = \text{true}$,
 $(\text{unknown or false}) = \text{unknown}$
 $(\text{unknown or unknown}) = \text{unknown}$
- AND: $(\text{true and unknown}) = \text{unknown}$,
 $(\text{false and unknown}) = \text{false}$,
 $(\text{unknown and unknown}) = \text{unknown}$
- NOT: $(\text{not unknown}) = \text{unknown}$
- In SQL “*P is unknown*” evaluates to true if predicate *P* evaluates to *unknown*

Result of select predicate is treated as *false* if it evaluates to *unknown*

Division Operation

Notation

$$r \div s$$

Defined as

Given relations $r(R)$ and $s(S)$, such that $S \subset R$,
 $r \div s$ is the largest relation $t(R-S)$ such that $t \times s \subseteq r$

E.g.

let $r(ID, course_id) = \prod_{ID, course_id} (takes)$ and
 $s(course_id) = \prod_{course_id} (\sigma_{dept_name="Biology"}(course))$

then $r \div s$ = students who have taken all courses in the Biology Dept.

Division Operation

	r	s	$r \div s$
A	B	B	A
α	1	1	
α	2	2	
α	3		
β	1		
γ	1		
δ	1		
δ	3		
δ	4		
ε	6		
ε	1		
β	2		

Express $r \div s$ using basic operations

$$\text{temp1} \leftarrow \prod_{R-S}(r)$$

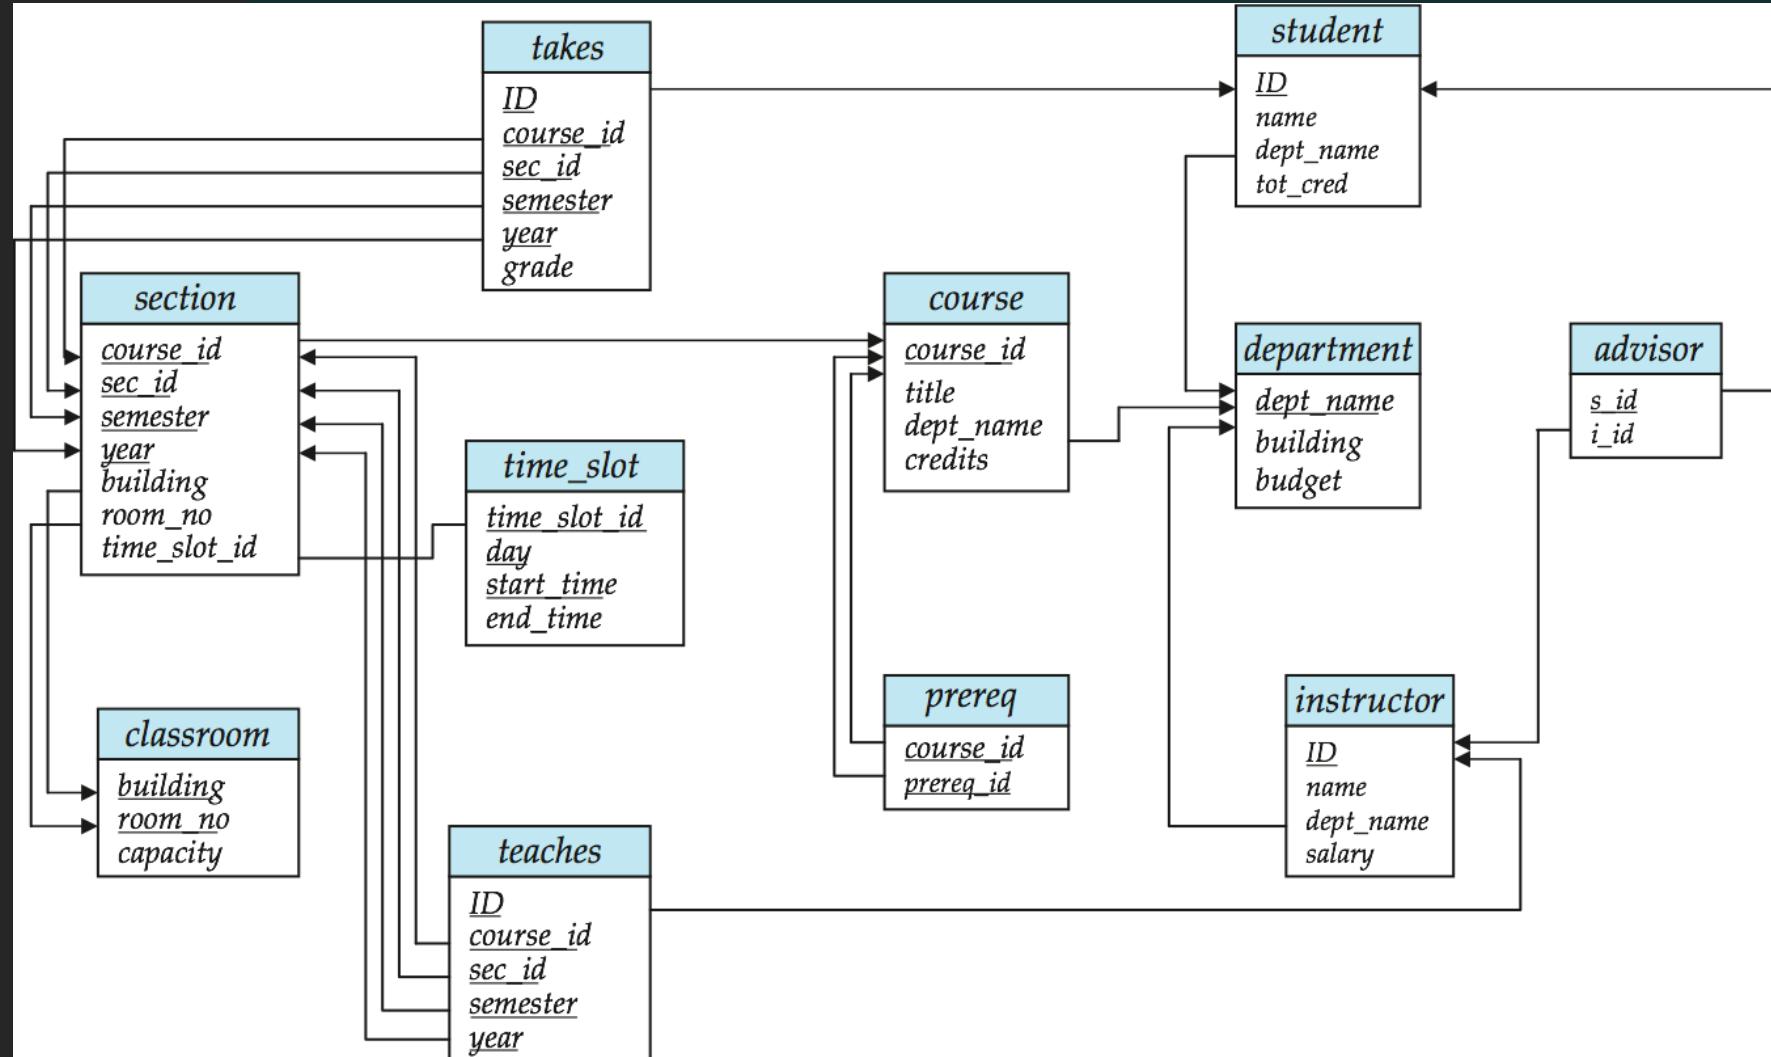

$$\text{temp2} \leftarrow \prod_{R-S}((\text{temp1} \times s) - \prod_{R-S,S}(r))$$

$$\text{temp1} - \text{temp2}$$

IF2IF2240 – Basis Data Formal Relational Query Language

Schema Diagram for University Database

Relational Algebra

Procedural language

Six basic operators

- select: σ
- project: Π
- union: \cup
- set difference: $-$
- cartesian product: \times
- rename: ρ

The operators take one or two relations as inputs
and produce a new relation as a result.

- Additional Operators

- Intersection: \cap
- natural join:
- assignment: \leftarrow
- outer join: \bowtie
- division: \div

- Extended Operators

- generalized projection
- aggregation

Extended Operations

Generalized Projection

· Notation

$$\prod_{F_1, F_2, \dots, F_n}(E)$$

E is any relational-algebra expression

Each of F_1, F_2, \dots, F_n are arithmetic expressions

· E.g.

Given relation *credit-info(customer-name, limit, credit-balance)*
find how much more each person can spend

$$\prod_{customer-name, limit - credit-balance} (credit-info)$$

Aggregate Functions and Operations (1)

Aggregate function

- **avg**: average value
- **min**: minimum value
- **max**: maximum value
- **sum**: sum of values
- **count**: number of values

Notation

$$G_1, G_2, \dots, G_n \text{ } \mathcal{G} \text{ } F_1(A_1), F_2(A_2), \dots, F_n(A_n) \text{ } (E)$$

The aggregated values do not have an attribute name; they can be given a name either by using the rename operator **p** or for convenience using the following syntax:

$$\mathcal{G} \text{ } F_1(A_1) \text{ as } <\text{attr-name}>$$

KNOWLEDGE & SOFTWARE ENGINEERING

Data Modifications

Deletion

Notation

$$r \leftarrow r - E$$

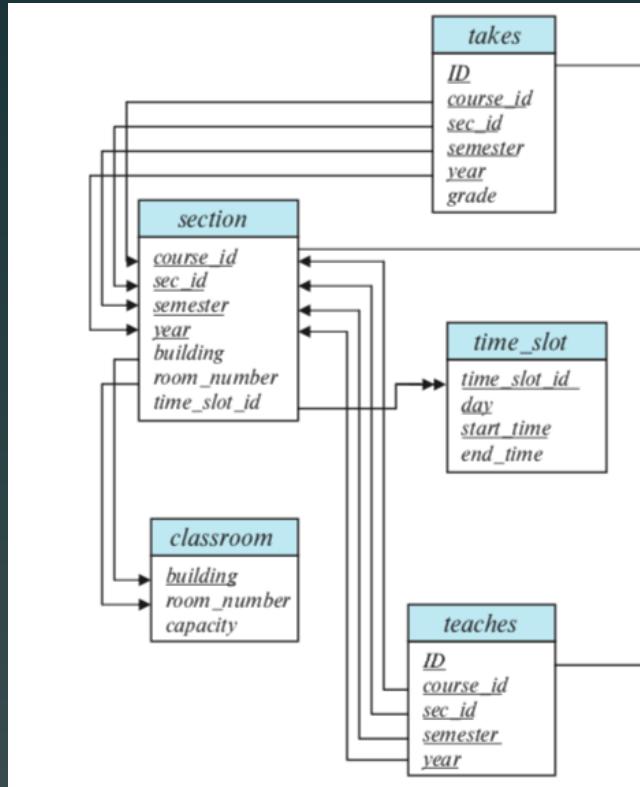

Example

`prereq (course_id, prereq_id)`

Delete all prerequisites of course "IF2240"

`prereq \leftarrow prereq - $\sigma_{course_id = "IF2240"}(prereq)$`

Deletion Examples

@Silberschatz et.al. (2020)

Delete the study plan of student with ID "13518000" for 1-2019 semester.

$takes \leftarrow takes - \sigma_{ID = "13518000" \wedge sem = 1 \wedge year = 2019} (takes)$

Delete all sections that was taught by instructor with ID "132132132" for 2-2019 semester.

$r_1 \leftarrow \sigma_{ID = "132132132" \wedge sem = 2 \wedge year = 2019} (teaches)$

$r_2 \leftarrow \prod_{course_id, sec_id, sem, year} (r_1) \bowtie takes$

$r_3 \leftarrow \prod_{course_id, sec_id, sem, year} (r_1) \bowtie section$

$teaches \leftarrow teaches - r_1$

$takes \leftarrow takes - r_2$

$section \leftarrow section - r_3$

Insertion

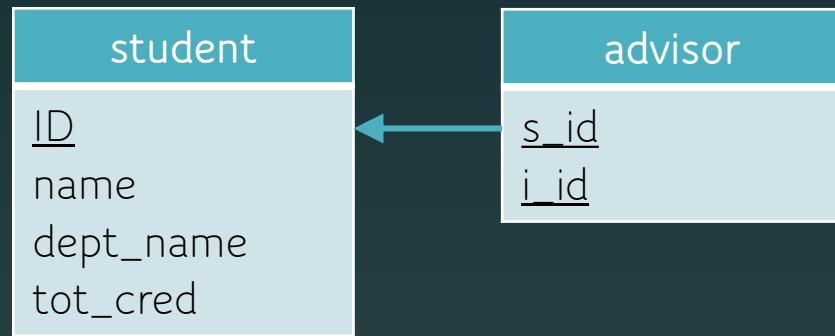

Types

- 1.specify a tuple to be inserted
- 2.write a query whose result is a set of tuples to be inserted

Notation

$$r \leftarrow r \cup E$$

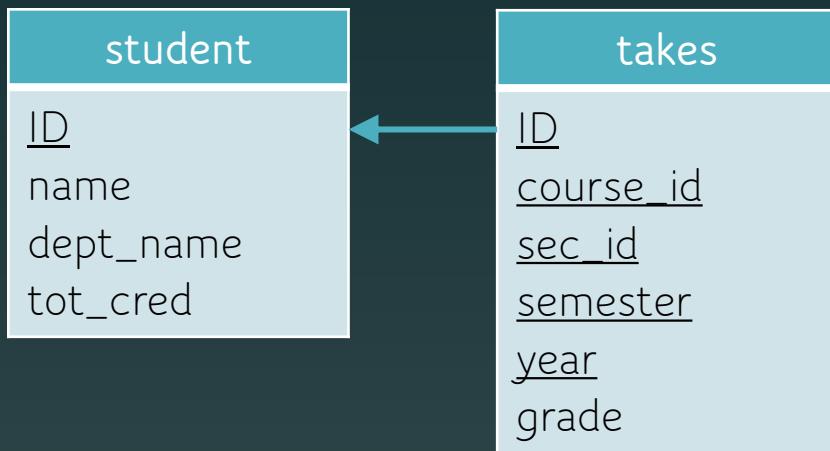

Insertion – Example 1

Insert information in the database specifying that a transfer student, Abdul, with ID 13518600 was enrolled to Comp. Sci. department with 36 total credit transfer and instructor 132132132 as his advisor.

$$\text{student} \leftarrow \text{student} \cup \{(13518600, "Abdul", "Comp. Sci.", 36)\}$$
$$\text{advisor} \leftarrow \text{advisor} \cup \{(13518600, 132132132)\}$$

Insertion – Example 2

All students from Comp. Sci. dept with less than 130 total credits are automatically enrolled to course IF4000 in 2-2019 semester (evenly distributed to 3 available section IDs: 1, 2, 3)

$$r_1 \leftarrow \sigma_{dept_name = "Comp.Sci." \wedge tot_cred < 130} (student)$$

$$takes \leftarrow takes \cup \Pi_{ID, "IF4000", ((ID-1) \text{ mod } 3)+1, 2, 2019, null} (r_1)$$

Updating

Use the generalized projection operator to do this task

$$r \leftarrow \Pi_{F_1, F_2, \dots, F_n}(r)$$

Each F_i is either

- the i^{th} attribute of r , if the i^{th} attribute is not updated, or,
- if the attribute is to be updated F_i is an expression, involving only constants and the attributes of r , which gives the new value for the attribute

Update Examples

instructor
ID
name
dept_name
salary

Give a 5% salary raise to all instructors.

$$\text{instructor} \leftarrow \prod_{ID, name, dept_name, salary * 1.05} (\text{instructor})$$

Give a 5% salary raise to those instructors who earn less than 70000.

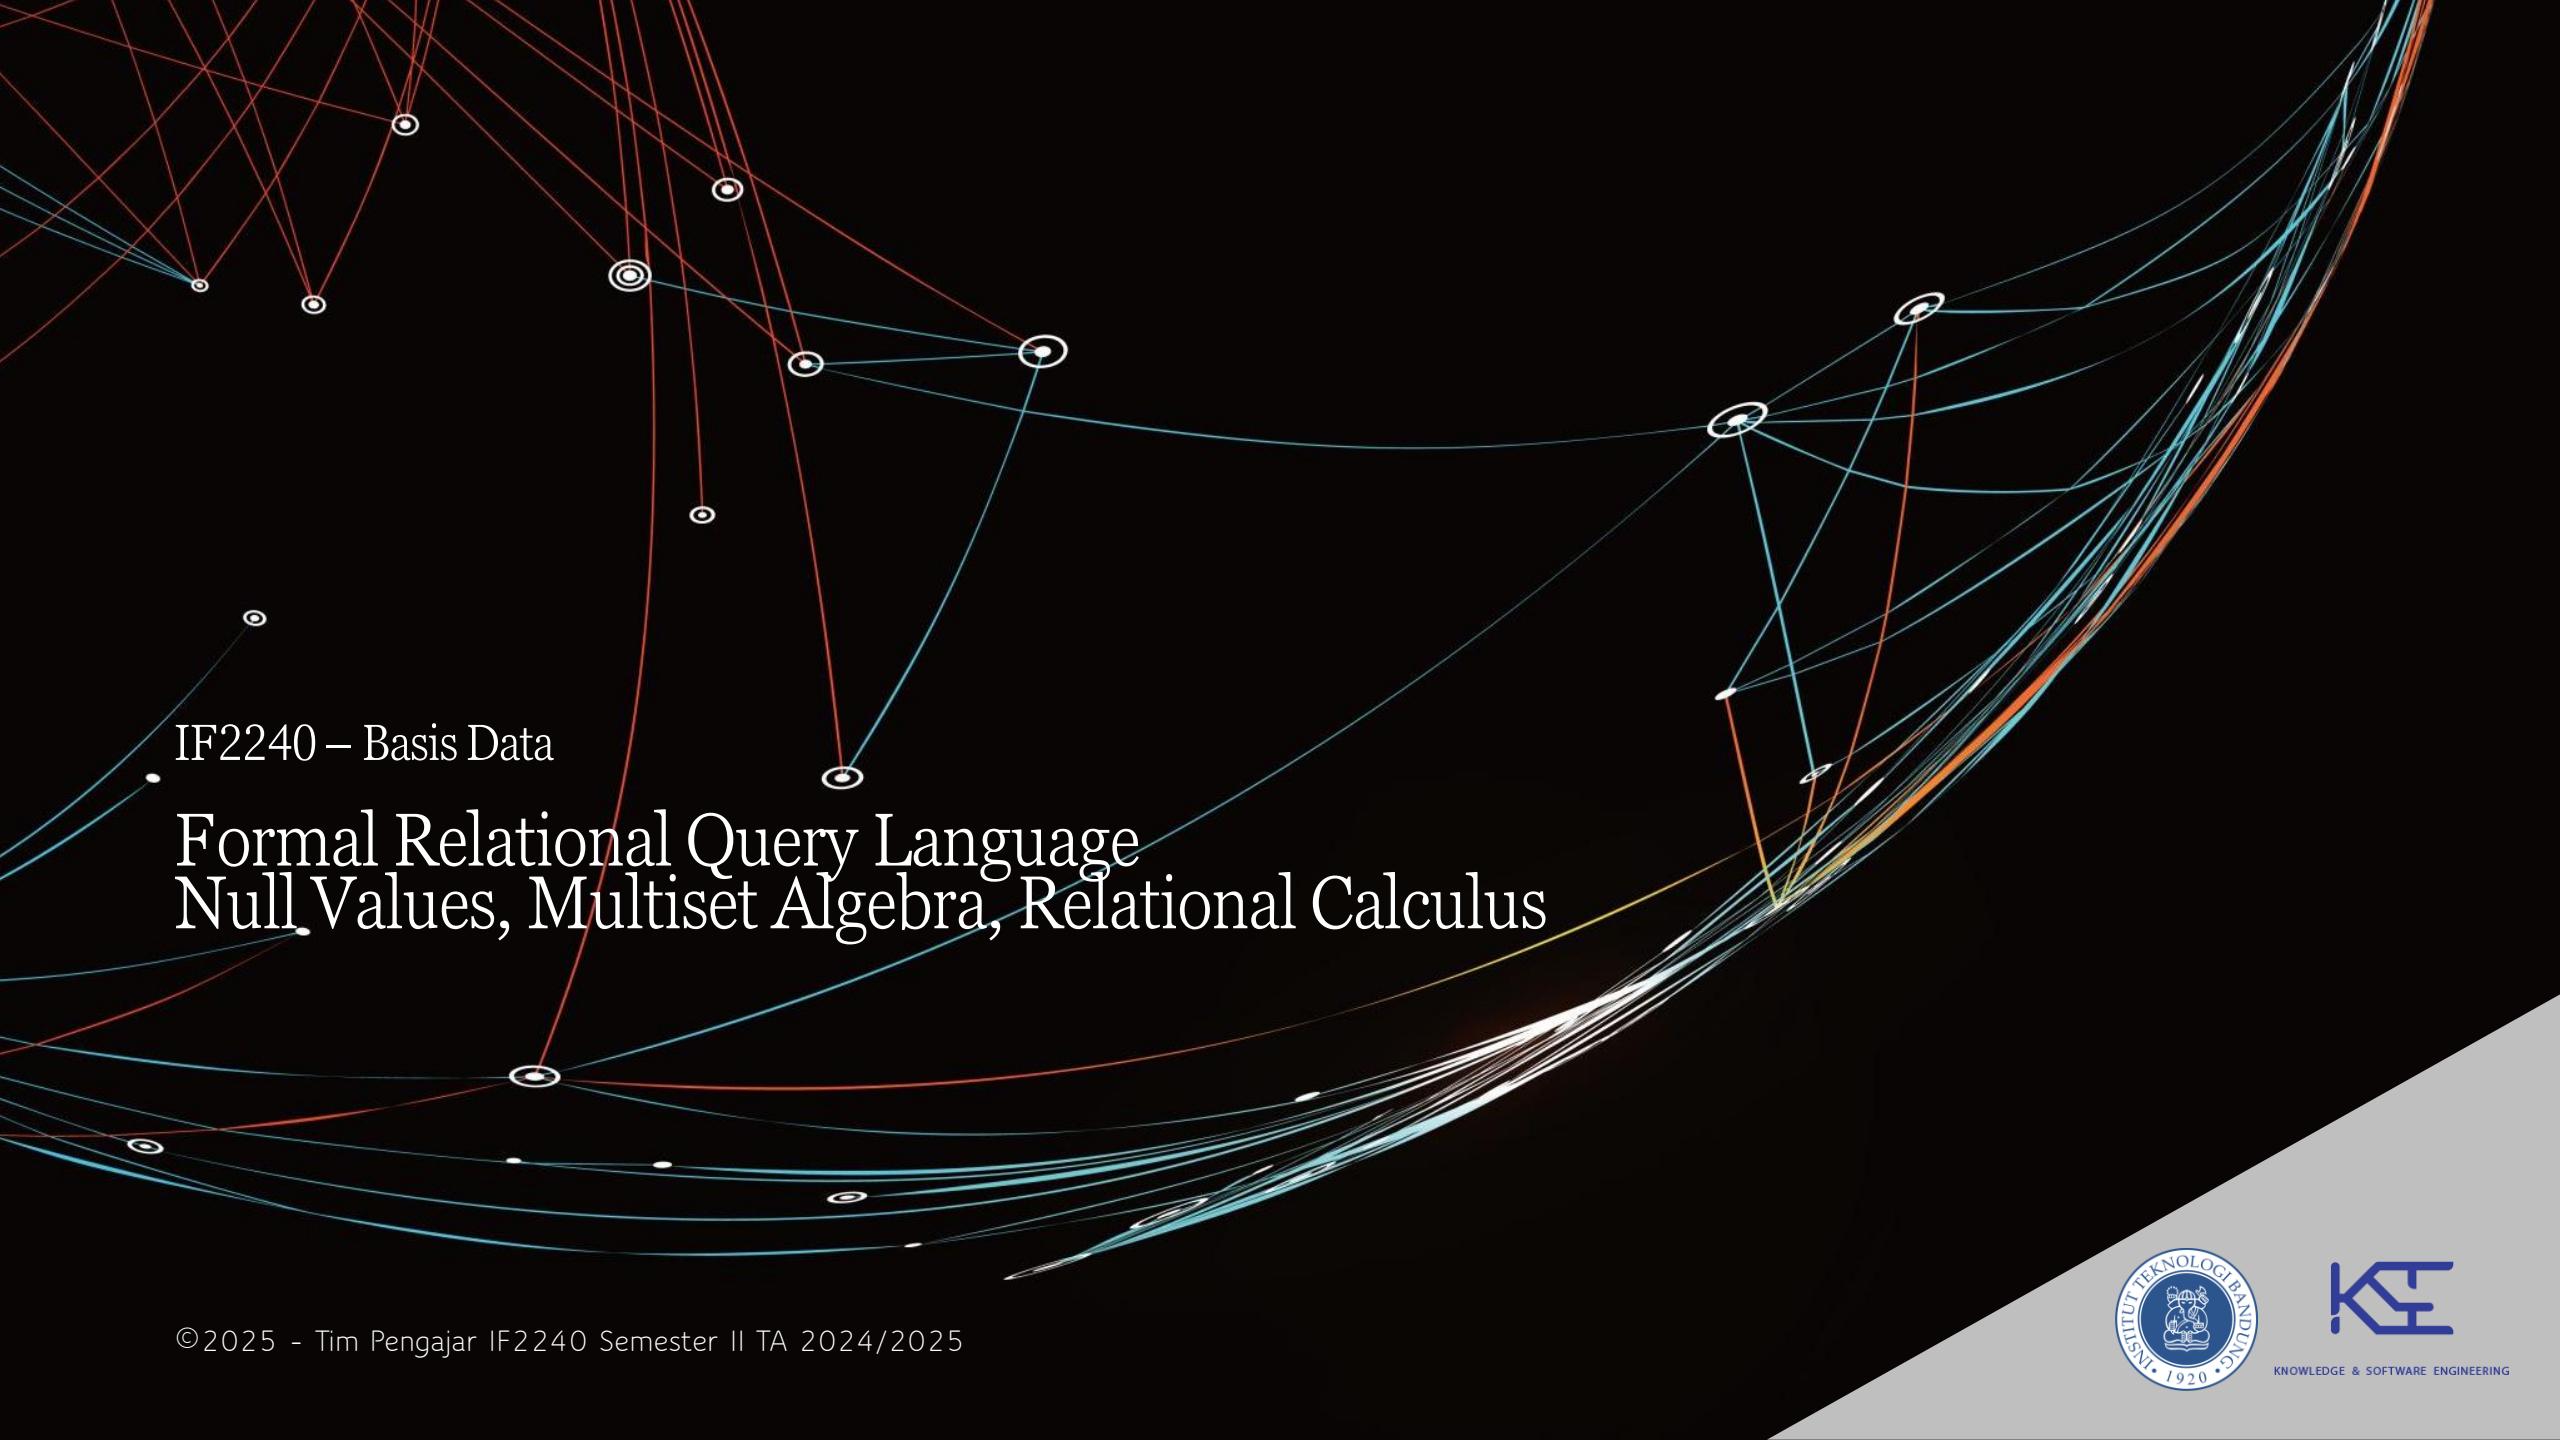

$$\text{instructor} \leftarrow \prod_{ID, name, dept_name, salary * 1.05} (\sigma_{\text{salary} < 70000} (\text{instructor}))$$

$$\cup \sigma_{\text{salary} \geq 70000} (\text{instructor})$$

Increase salaries of instructors whose salary is over \$70,000 by 3%, and all others receive a 5% raise.

$$\text{instructor} \leftarrow \prod_{ID, name, dept_name, salary * 1.05} (\sigma_{\text{salary} \leq 70000} (\text{instructor}))$$

$$\cup \prod_{ID, name, dept_name, salary * 1.03} (\sigma_{\text{salary} > 70000} (\text{instructor}))$$

The background of the slide features a complex network of abstract lines in various colors (red, cyan, orange, yellow) on a black background. Small circular nodes with a central dot are scattered throughout the network, connected by the lines.

- Chapter 2: Relational Model
 - Section 2.6. The Relational Algebra
- Chapter 27: Formal-Relational Query Languages (*online chapter*)
 - Section 27.1. The Tuple Relational Calculus
 - Section 27.2. The Domain Relational Calculus

Null Values

It is possible for tuples to have a null value, denoted by *null*, for some of their attributes

null signifies an unknown value or that a value does not exist.

The result of any arithmetic expression involving *null* is *null*.

Aggregate functions simply ignore null values (as in SQL)

For duplicate elimination and grouping, null is treated like any other value, and two nulls are assumed to be the same (as in SQL)

Null Values

Comparisons with null values return the special truth value: *unknown*

- If *false* was used instead of *unknown*, then *not (A < 5)*
would not be equivalent to *A >= 5*

Three-valued logic using the truth value *unknown*:

- OR: (*unknown or true*) = *true*,
 (*unknown or false*) = *unknown*
 (*unknown or unknown*) = *unknown*
- AND: (*true and unknown*) = *unknown*,
 (*false and unknown*) = *false*,
 (*unknown and unknown*) = *unknown*
- NOT: (*not unknown*) = *unknown*
- In SQL “*P is unknown*” evaluates to true if predicate *P* evaluates to *unknown*

Result of select predicate is treated as *false* if it evaluates to *unknown*

Multiset Relational Algebra

Pure relational algebra removes all duplicates

- e.g. after projection

Multiset relational algebra retains duplicates, to match SQL semantics

- SQL duplicate retention was initially for efficiency, but is now a feature

Multiset relational algebra defined as follows

- selection: has as many duplicates of a tuple as in the input, if the tuple satisfies the selection
- projection: one tuple per input tuple, even if it is a duplicate
- cross product: If there are m copies of t_1 in r , and n copies of t_2 in s , there are $m \times n$ copies of $t_1.t_2$ in $r \times s$
- Other operators similarly defined
 - E.g. union: $m + n$ copies, intersection: $\min(m, n)$ copies
 - difference: $\min(0, m - n)$ copies

Relational Calculus

Tuple Relational Calculus

A nonprocedural query language, where each query is of the form

$$\{t \mid P(t)\}$$

It is the set of all tuples t such that predicate P is true for t

t is a *tuple variable*, $t[A]$ denotes the value of tuple t on attribute A

$t \in r$ denotes that tuple t is in relation r

P is a *formula* similar to that of the predicate calculus

Predicate Calculus Formula

1. Set of attributes and constants
2. Set of comparison operators: (e.g., $<$, \leq , $=$, \neq , $>$, \geq)
3. Set of connectives: and (\wedge), or (\vee), not (\neg)
4. Implication (\Rightarrow): $x \Rightarrow y$, if x is true, then y is true

$$x \Rightarrow y \equiv \neg x \vee y$$

5. Set of quantifiers:

- ▶ $\exists t \in r (Q(t)) \equiv$ "there exists" a tuple t in relation r such that predicate $Q(t)$ is true
- ▶ $\forall t \in r (Q(t)) \equiv Q$ is true "for all" tuples t in relation r

Example Queries

Find the *ID*, *name*, *dept_name*, *salary* for instructors whose salary is greater than \$80,000

$$\{t \mid t \in \text{instructor} \wedge t[\text{salary}] > 80000\}$$

As in the previous query, but output only the *ID* attribute value

$$\{t \mid \exists s \in \text{instructor} (t[\text{ID}] = s[\text{ID}] \wedge s[\text{salary}] > 80000)\}$$

Notice that a relation on schema (*ID*) is implicitly defined by the query

Example Queries

Find the names of all instructors whose department is in the Watson building

$$\{t \mid \exists s \in \text{instructor} (t[\text{name}] = s[\text{name}] \wedge \exists u \in \text{department} (u[\text{dept_name}] = s[\text{dept_name}] \wedge u[\text{building}] = \text{"Watson"}))\}$$

Find the set of all courses taught in the Fall 2017 semester, or in the Spring 2018 semester, or both

$$\{t \mid \exists s \in \text{section} (t[\text{course_id}] = s[\text{course_id}] \wedge s[\text{semester}] = \text{"Fall"} \wedge s[\text{year}] = 2017) \vee \exists u \in \text{section} (t[\text{course_id}] = u[\text{course_id}] \wedge u[\text{semester}] = \text{"Spring"} \wedge u[\text{year}] = 2018)\}$$

Example Queries

Find the set of all courses taught in the Fall 2017 semester, and in the Spring 2018 semester

$$\{t \mid \exists s \in \text{section} (t[\text{course_id}] = s[\text{course_id}] \wedge s[\text{semester}] = \text{"Fall"} \wedge s[\text{year}] = 2017) \\ \wedge \exists u \in \text{section} (t[\text{course_id}] = u[\text{course_id}] \wedge u[\text{semester}] = \text{"Spring"} \wedge u[\text{year}] = 2018)\}$$

Find the set of all courses taught in the Fall 2017 semester, but not in the Spring 2018 semester

$$\{t \mid \exists s \in \text{section} (t[\text{course_id}] = s[\text{course_id}] \wedge s[\text{semester}] = \text{"Fall"} \wedge s[\text{year}] = 2017) \\ \wedge \neg \exists u \in \text{section} (t[\text{course_id}] = u[\text{course_id}] \wedge u[\text{semester}] = \text{"Spring"} \wedge u[\text{year}] = 2018)\}$$

Safety of Expressions

It is possible to write tuple calculus expressions that generate infinite relations.

For example, $\{ t \mid \neg t \in r \}$ results in an infinite relation if the domain of any attribute of relation r is infinite

To guard against the problem, we restrict the set of allowable expressions to safe expressions.

An expression $\{t \mid P(t)\}$ in the tuple relational calculus is *safe* if every component of t appears in one of the relations, tuples, or constants that appear in P

- NOTE: this is more than just a syntax condition.
 - E.g. $\{ t \mid t[A] = 5 \vee \text{true} \}$ is not safe --- it defines an infinite set with attribute values that do not appear in any relation or tuples or constants in P .

Universal Quantification

Find all students who have taken all courses offered in the Biology department

$$\{t \mid \exists r \in \text{student} (t [\text{ID}] = r [\text{ID}]) \wedge \\ (\forall u \in \text{course} (u [\text{dept_name}] = \text{"Biology"} \Rightarrow \\ \exists s \in \text{takes} (t [\text{ID}] = s [\text{ID}] \wedge \\ s [\text{course_id}] = u [\text{course_id}]))\}$$

- Note that without the existential quantification on student, the above query would be unsafe if the Biology department has not offered any courses.

Domain Relational Calculus

A nonprocedural query language equivalent in power to the tuple relational calculus

Each query is an expression of the form:

$$\{ < x_1, x_2, \dots, x_n > \mid P(x_1, x_2, \dots, x_n) \}$$

- x_1, x_2, \dots, x_n represent domain variables
- P represents a formula similar to that of the predicate calculus

Example Queries

Find the *ID, name, dept_name, salary* for instructors whose salary is greater than \$80,000

{ $< i, n, d, s >$ | $< i, n, d, s > \in \text{instructor} \wedge s > 80000$ }

As in the previous query, but output only the *ID* attribute value

{ $< i >$ | $\exists n, d, s (< i, n, d, s > \in \text{instructor} \wedge s > 80000)$ }

Find the names of all instructors whose department is in the Watson building

{ $< n >$ | $\exists i, d, s (< i, n, d, s > \in \text{instructor}$
 $\wedge \exists b, a (< d, b, a > \in \text{department} \wedge b = \text{"Watson"})$ }

Example Queries

Find the set of all courses taught in the Fall 2017 semester, or in the Spring 2018 semester, or both

$$\{<C> \mid \exists a, s, y, b, r, t \ (<C, a, s, y, b, r, t> \in \text{section} \wedge \\ s = \text{"Fall"} \wedge y = 2017) \\ \vee \exists a, s, y, b, r, t \ (<C, a, s, y, b, r, t> \in \text{section}] \wedge \\ s = \text{"Spring"} \wedge y = 2018)\}$$

This case can also be written as

$$\{<C> \mid \exists a, s, y, b, r, t \ (<C, a, s, y, b, r, t> \in \text{section} \wedge \\ ((s = \text{"Fall"} \wedge y = 2017) \vee (s = \text{"Spring"} \wedge y = 2018))\}$$

Find the set of all courses taught in the Fall 2017 semester, and in the Spring 2018 semester

$$\{<C> \mid \exists a, s, y, b, r, t \ (<C, a, s, y, b, r, t> \in \text{section} \wedge \\ s = \text{"Fall"} \wedge y = 2017) \\ \wedge \exists a, s, y, b, r, t \ (<C, a, s, y, b, r, t> \in \text{section}] \wedge \\ s = \text{"Spring"} \wedge y = 2018)\}$$

Safety of Expressions

The expression:

$$\{ < x_1, x_2, \dots, x_n > \mid P(x_1, x_2, \dots, x_n) \}$$

is safe if all of the following hold:

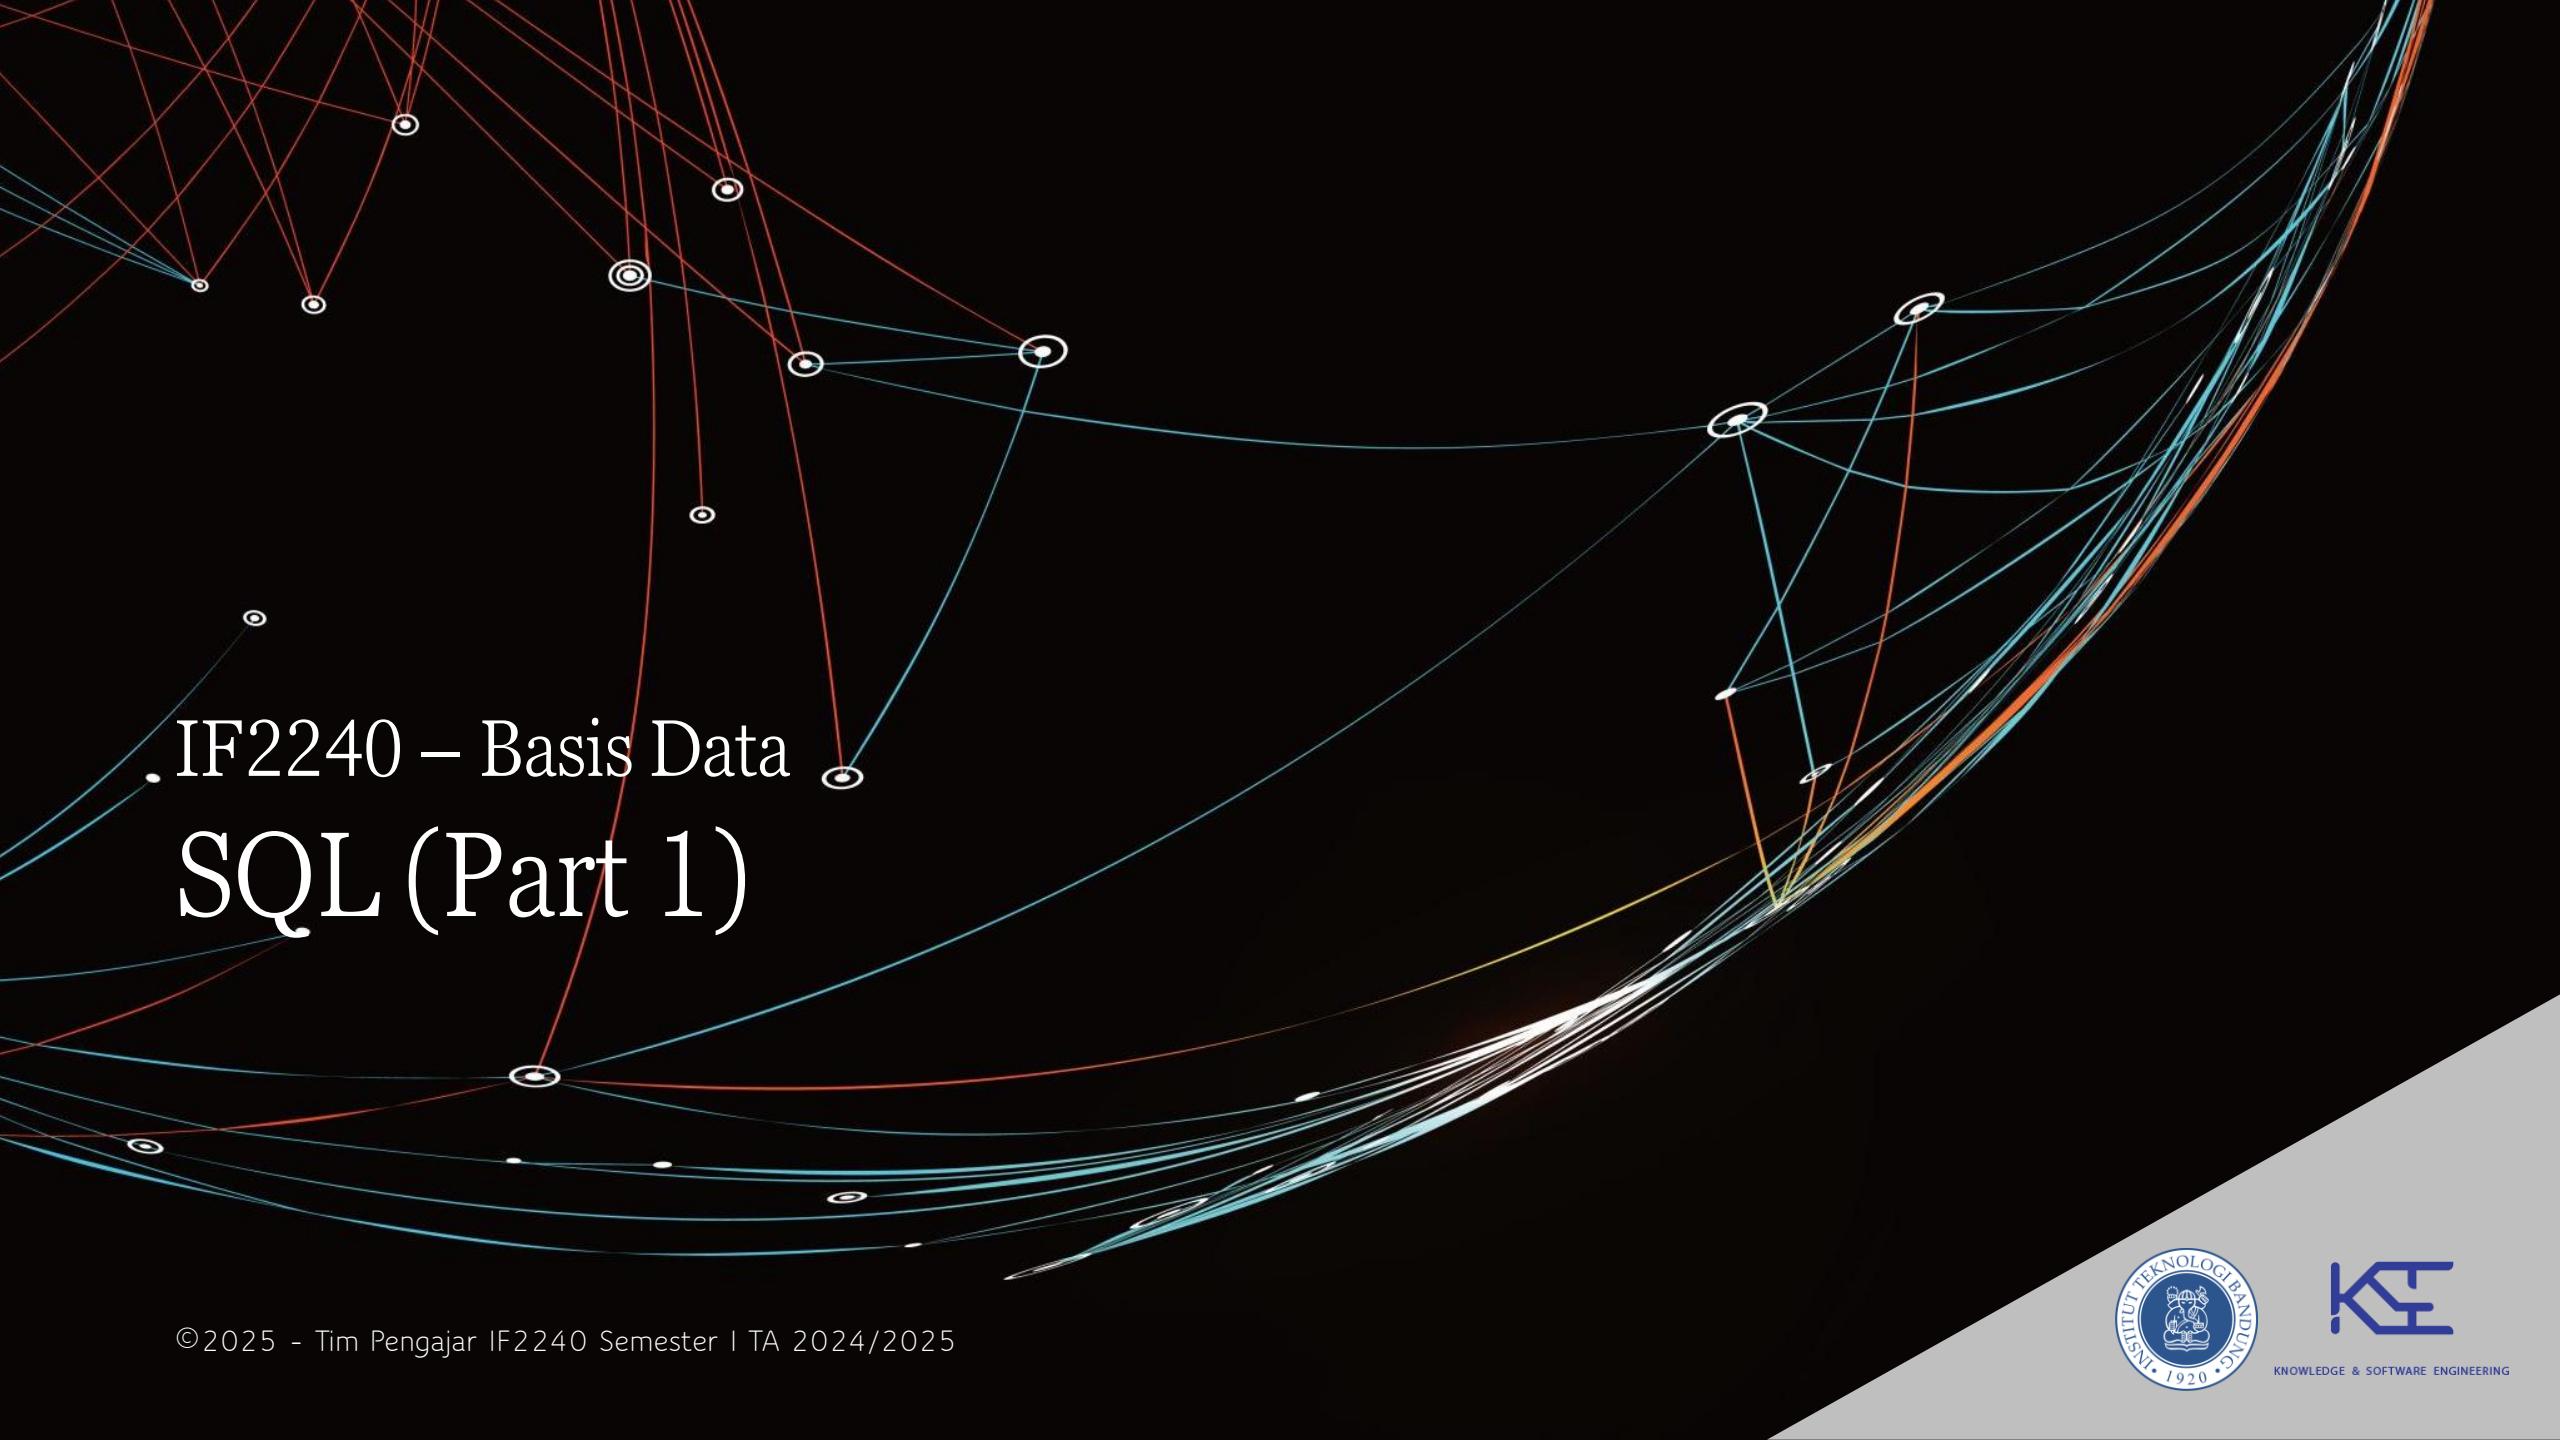

1. All values that appear in tuples of the expression are values from $\text{dom}(P)$ (that is, the values appear either in P or in a tuple of a relation mentioned in P).
2. For every “there exists” subformula of the form $\exists x (P_1(x))$, the subformula is true if and only if there is a value of x in $\text{dom}(P_1)$ such that $P_1(x)$ is true.
3. For every “for all” subformula of the form $\forall x (P_1(x))$, the subformula is true if and only if $P_1(x)$ is true for all values x from $\text{dom}(P_1)$.

Universal Quantification

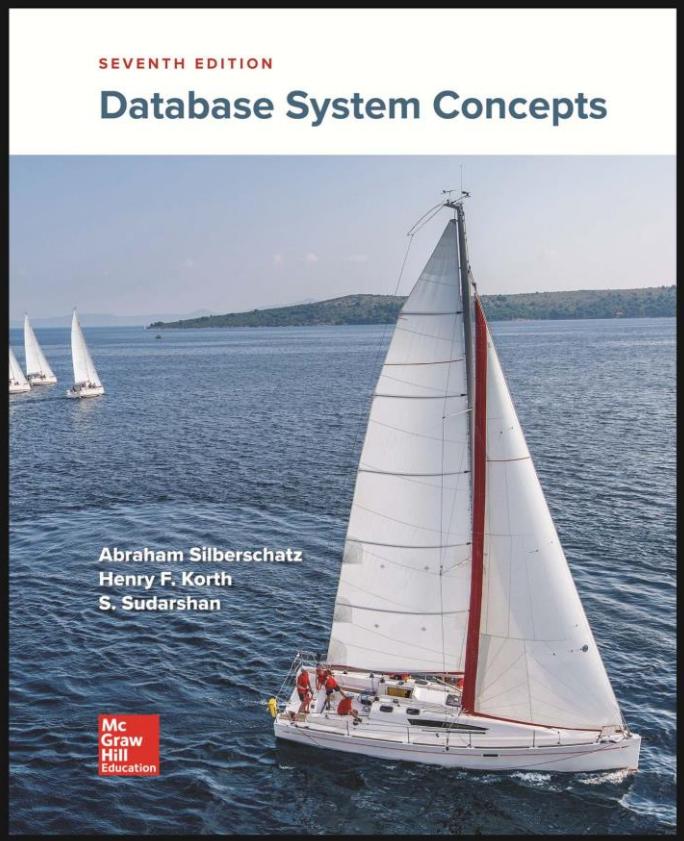

Find all students who have taken all courses offered in the Biology department

$$\{ < i > \mid \exists n, d, tc (< i, n, d, tc > \in \text{student} \wedge \\ (\forall ci, ti, dn, cr (< ci, ti, dn, cr > \in \text{course} \wedge dn = \text{"Biology"} \\ \Rightarrow \exists si, se, y, g (< i, ci, si, se, y, g > \in \text{takes}))) \}$$

- Note that without the existential quantification on student, the above query would be unsafe if the Biology department has not offered any courses.

IF2240 – Basis Data SQL (Part 1)

Sumber

Silberschatz, Korth, Sudarshan: "Database System Concepts", 7th Edition

- Chapter 3 : Introduction to SQL

History

IBM Sequel language developed as part of System R project at the IBM San Jose Research Laboratory

Renamed Structured Query Language (SQL)

ANSI and ISO standard SQL:

- SQL-86
- SQL-89
- SQL-92
- SQL:1999 (language name became Y2K compliant!)
- SQL:2003

Commercial systems offer most, if not all, SQL-92 features, plus varying feature sets from later standards and special proprietary features.

- Not all examples here may work on your particular system.

KNOWLEDGE & SOFTWARE ENGINEERING

SQL Parts

DML -- provides the ability to query information from the database and to insert tuples into, delete tuples from, and modify tuples in the database.

integrity - the DDL includes commands for specifying integrity constraints.

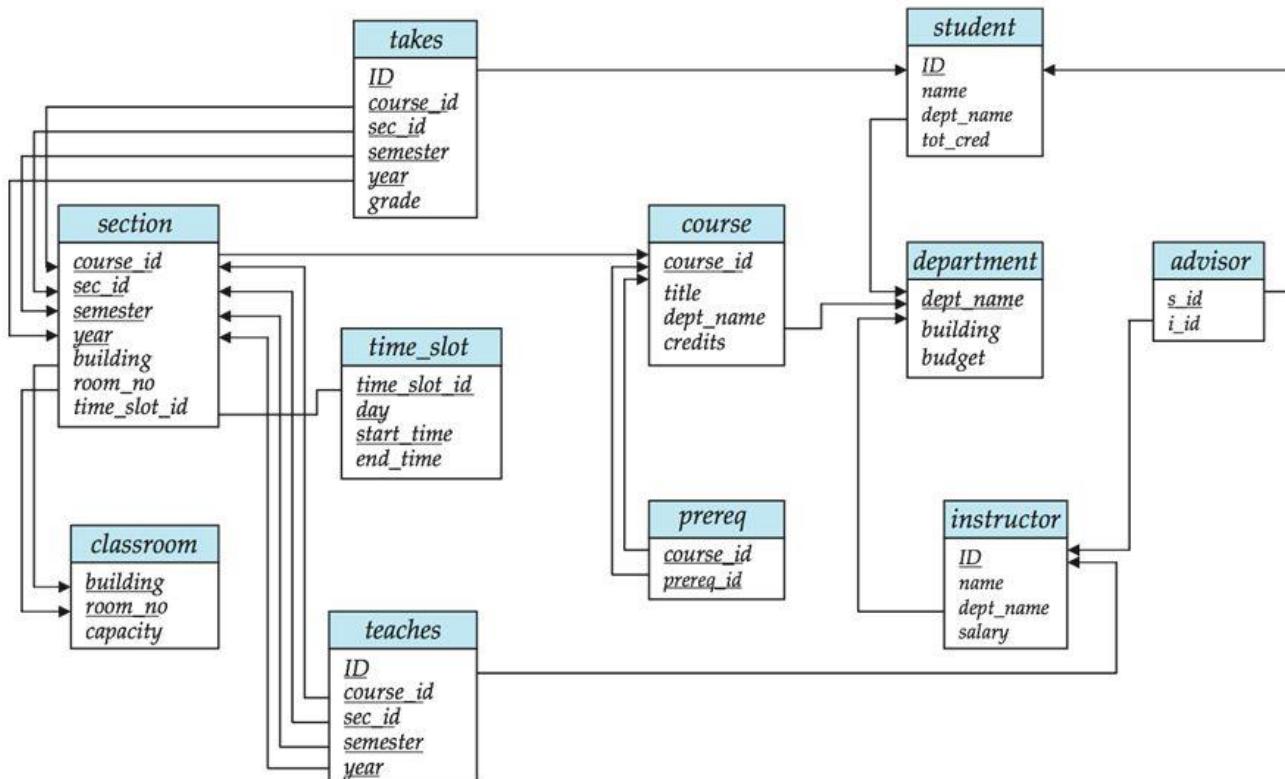

View definition -- The DDL includes commands for defining views.

Transaction control -includes commands for specifying the beginning and ending of transactions.

Embedded SQL and dynamic SQL -- define how SQL statements can be embedded within general-purpose programming languages.

Authorization - includes commands for specifying access rights to relations and views.

Schema Diagram

Basic Query Structure

A typical SQL query has the form:

```
select  $A_1, A_2, \dots, A_n$ 
from  $r_1, r_2, \dots, r_m$ 
where  $P$ 
```

- A_i represents an attribute
- R_i represents a relation
- P is a predicate.

The result of an SQL query is a relation.

The select Clause

The **select** clause lists the attributes desired in the result of a query

- corresponds to the projection operation of the relational algebra

Example: find the names of all instructors:

```
select name  
      from instructor
```

NOTE: SQL names are case insensitive (i.e., you may use upper- or lower-case letters.)

- E.g., $Name \equiv NAME \equiv name$
- Some people use upper case wherever we use bold font.

The select Clause (Cont.)

SQL allows duplicates in relations as well as in query results.

To force the elimination of duplicates, insert the keyword **distinct** after **select**.

Find the department names of all instructors, and remove duplicates

```
select distinct dept_name  
from instructor
```

The keyword **all** specifies that duplicates should not be removed.

```
select all dept_name  
from instructor
```

dept_name
Comp. Sci.
Finance
Music
Physics
History
Physics
Comp. Sci.
History
Finance
Biology
Comp. Sci.
Elec. Eng.

The select Clause (Cont.)

An asterisk in the select clause denotes “all attributes”

```
select *  
from instructor
```

An attribute can be a literal with no **from** clause : **select** '437'

- Results is a table with one column and a single row with value “437”
- Can give the column a name using:

```
select '437' as FOO
```

An attribute can be a literal with **from** clause

```
select 'A'  
from instructor
```

- Result is a table with one column and N rows (number of tuples in the *instructors* table), each row with value “A”

KNOWLEDGE & SOFTWARE ENGINEERING

The select Clause (Cont.)

The **select** clause can contain arithmetic expressions involving the operation, +, -, *, and /, and operating on constants or attributes of tuples.

- The query:

```
select ID, name, salary/12  
      from instructor
```

would return a relation that is the same as the *instructor* relation, except that the value of the attribute *salary* is divided by 12.

- Can rename “*salary/12*” using the **as** clause:

```
select ID, name, salary/12 as monthly_salary
```

The where Clause

The **where** clause specifies conditions that the result must satisfy

- Corresponds to the selection predicate of the relational algebra.

To find all instructors in Comp. Sci. dept

```
select name  
from instructor  
where dept_name = 'Comp. Sci.'
```

SQL allows the use of the logical connectives **and**, **or**, and **not**. The operands of the logical connectives can be expressions involving the comparison operators <, <=, >, >=, =, and <>. Comparisons can be applied to results of arithmetic expressions

To find all instructors in Comp. Sci. dept with salary > 70000

```
select name  
from instructor  
where dept_name = 'Comp. Sci.' and salary > 70000
```

name
Katz
Brandt

The from Clause

The **from** clause lists the relations involved in the query

- Corresponds to the Cartesian product operation of the relational algebra.

Find the Cartesian product *instructor X teaches*

```
select *
  from instructor, teaches
```

- generates every possible instructor – teaches pair, with all attributes from both relations.
- For common attributes (e.g., *ID*), the attributes in the resulting table are renamed using the relation name (e.g., *instructor.ID*)

Cartesian product not very useful directly, but useful combined with where-clause condition (selection operation in relational algebra).

Examples

Find the names of all instructors who have taught some course and the course_id

- `select name, course_id
from instructor , teaches
where instructor.ID = teaches.ID`

Find the names of all instructors in the Art department who have taught some course and the course_id

- `select name, course_id
from instructor , teaches
where instructor.ID = teaches.ID
and instructor.dept_name = 'Art'`

<i>name</i>	<i>course_id</i>
Srinivasan	CS-101
Srinivasan	CS-315
Srinivasan	CS-347
Wu	FIN-201
Mozart	MU-199
Einstein	PHY-101
El Said	HIS-351
Katz	CS-101
Katz	CS-319
Crick	BIO-101
Crick	BIO-301
Brandt	CS-190
Brandt	CS-190
Brandt	CS-319
Kim	EE-181

The Rename Operation

The SQL allows renaming relations and attributes using the **as** clause:

old-name as new-name

Find the names of all instructors who have a higher salary than some instructor in 'Comp. Sci'.

- **select distinct *T.name***
from *instructor as T, instructor as S*
where *T.salary > S.salary and S.dept_name = 'Comp. Sci.'*

Keyword **as** is optional and may be omitted

instructor as T ≡ *instructor T*

Self “Join” Example

Relation *emp-super*

<i>person</i>	<i>supervisor</i>
Bob	Alice
Mary	Susan
Alice	David
David	Mary

Find the supervisor of “Bob”

Find the supervisor of the supervisor of “Bob”

Can you find ALL the supervisors (direct and indirect) of “Bob”?

String Operations

SQL includes a string-matching operator for comparisons on character strings. The operator **like** uses patterns that are described using two special characters:

- percent (%). The % character matches any substring.
- underscore (_). The _ character matches any character.

Find the names of all instructors whose name includes the substring "dar".

```
select name  
from instructor  
where name like '%dar%'
```

Match the string "100%"

```
like '100 \%' escape '\'
```

in that above we use backslash (\) as the escape character.

String Operations (Cont.)

Patterns are case sensitive.

Pattern matching examples:

- 'Intro%' matches any string beginning with "Intro".
- '%Comp%' matches any string containing "Comp" as a substring.
- '_ _ _' matches any string of exactly three characters.
- '_ _ _ %' matches any string of at least three characters.

SQL supports a variety of string operations such as

- concatenation (using "||")
- converting from upper to lower case (and vice versa)
- finding string length, extracting substrings, etc.

Ordering the Display of Tuples

List in alphabetic order the names of all instructors

```
select distinct name
from    instructor
order by name
```

We may specify **desc** for descending order or **asc** for ascending order, for each attribute; ascending order is the default.

- Example: `order by name desc`

Can sort on multiple attributes

- Example: `order by dept_name, name`

Where Clause Predicates

SQL includes a **between** comparison operator

Example: Find the names of all instructors with salary between \$90,000 and \$100,000 (that is, $\geq \$90,000$ and $\leq \$100,000$)

- `select name
from instructor
where salary between 90000 and 100000`

Tuple comparison

- `select name, course_id
from instructor, teaches
where (instructor.ID, dept_name) = (teaches.ID, 'Biology');`

Set Operations

- Find courses that ran in Fall 2017 **or** in Spring 2018

```
(select course_id from section where sem = 'Fall' and year = 2017)
union
(select course_id from section where sem = 'Spring' and year = 2018)
```

- Find courses that ran in Fall 2017 **and** in Spring 2018

```
(select course_id from section where sem = 'Fall' and year = 2017)
intersect
(select course_id from section where sem = 'Spring' and year = 2018)
```

- Find courses that ran in Fall 2017 **but not in** Spring 2018

```
(select course_id from section where sem = 'Fall' and year = 2017)
except
(select course_id from section where sem = 'Spring' and year = 2018)
```

Set Operations (Cont.)

Set operations **union**, **intersect**, and **except**

- Each of the above operations automatically eliminates duplicates

To retain all duplicates use the

- **union all**,
- **intersect all**
- **except all**.

Null Values

It is possible for tuples to have a null value, denoted by **null**, for some of their attributes

null signifies an unknown value or that a value does not exist.

The result of any arithmetic expression involving **null** is **null**

- Example: $5 + \text{null}$ returns **null**

The predicate **is null** can be used to check for null values.

- Example: Find all instructors whose salary is null.

```
select name  
from instructor  
where salary is null
```

The predicate **is not null** succeeds if the value on which it is applied is not null.

Null Values (Cont.)

SQL treats as **unknown** the result of any comparison involving a null value (other than predicates **is null** and **is not null**).

- Example: $5 < \text{null}$ or $\text{null} <> \text{null}$ or $\text{null} = \text{null}$

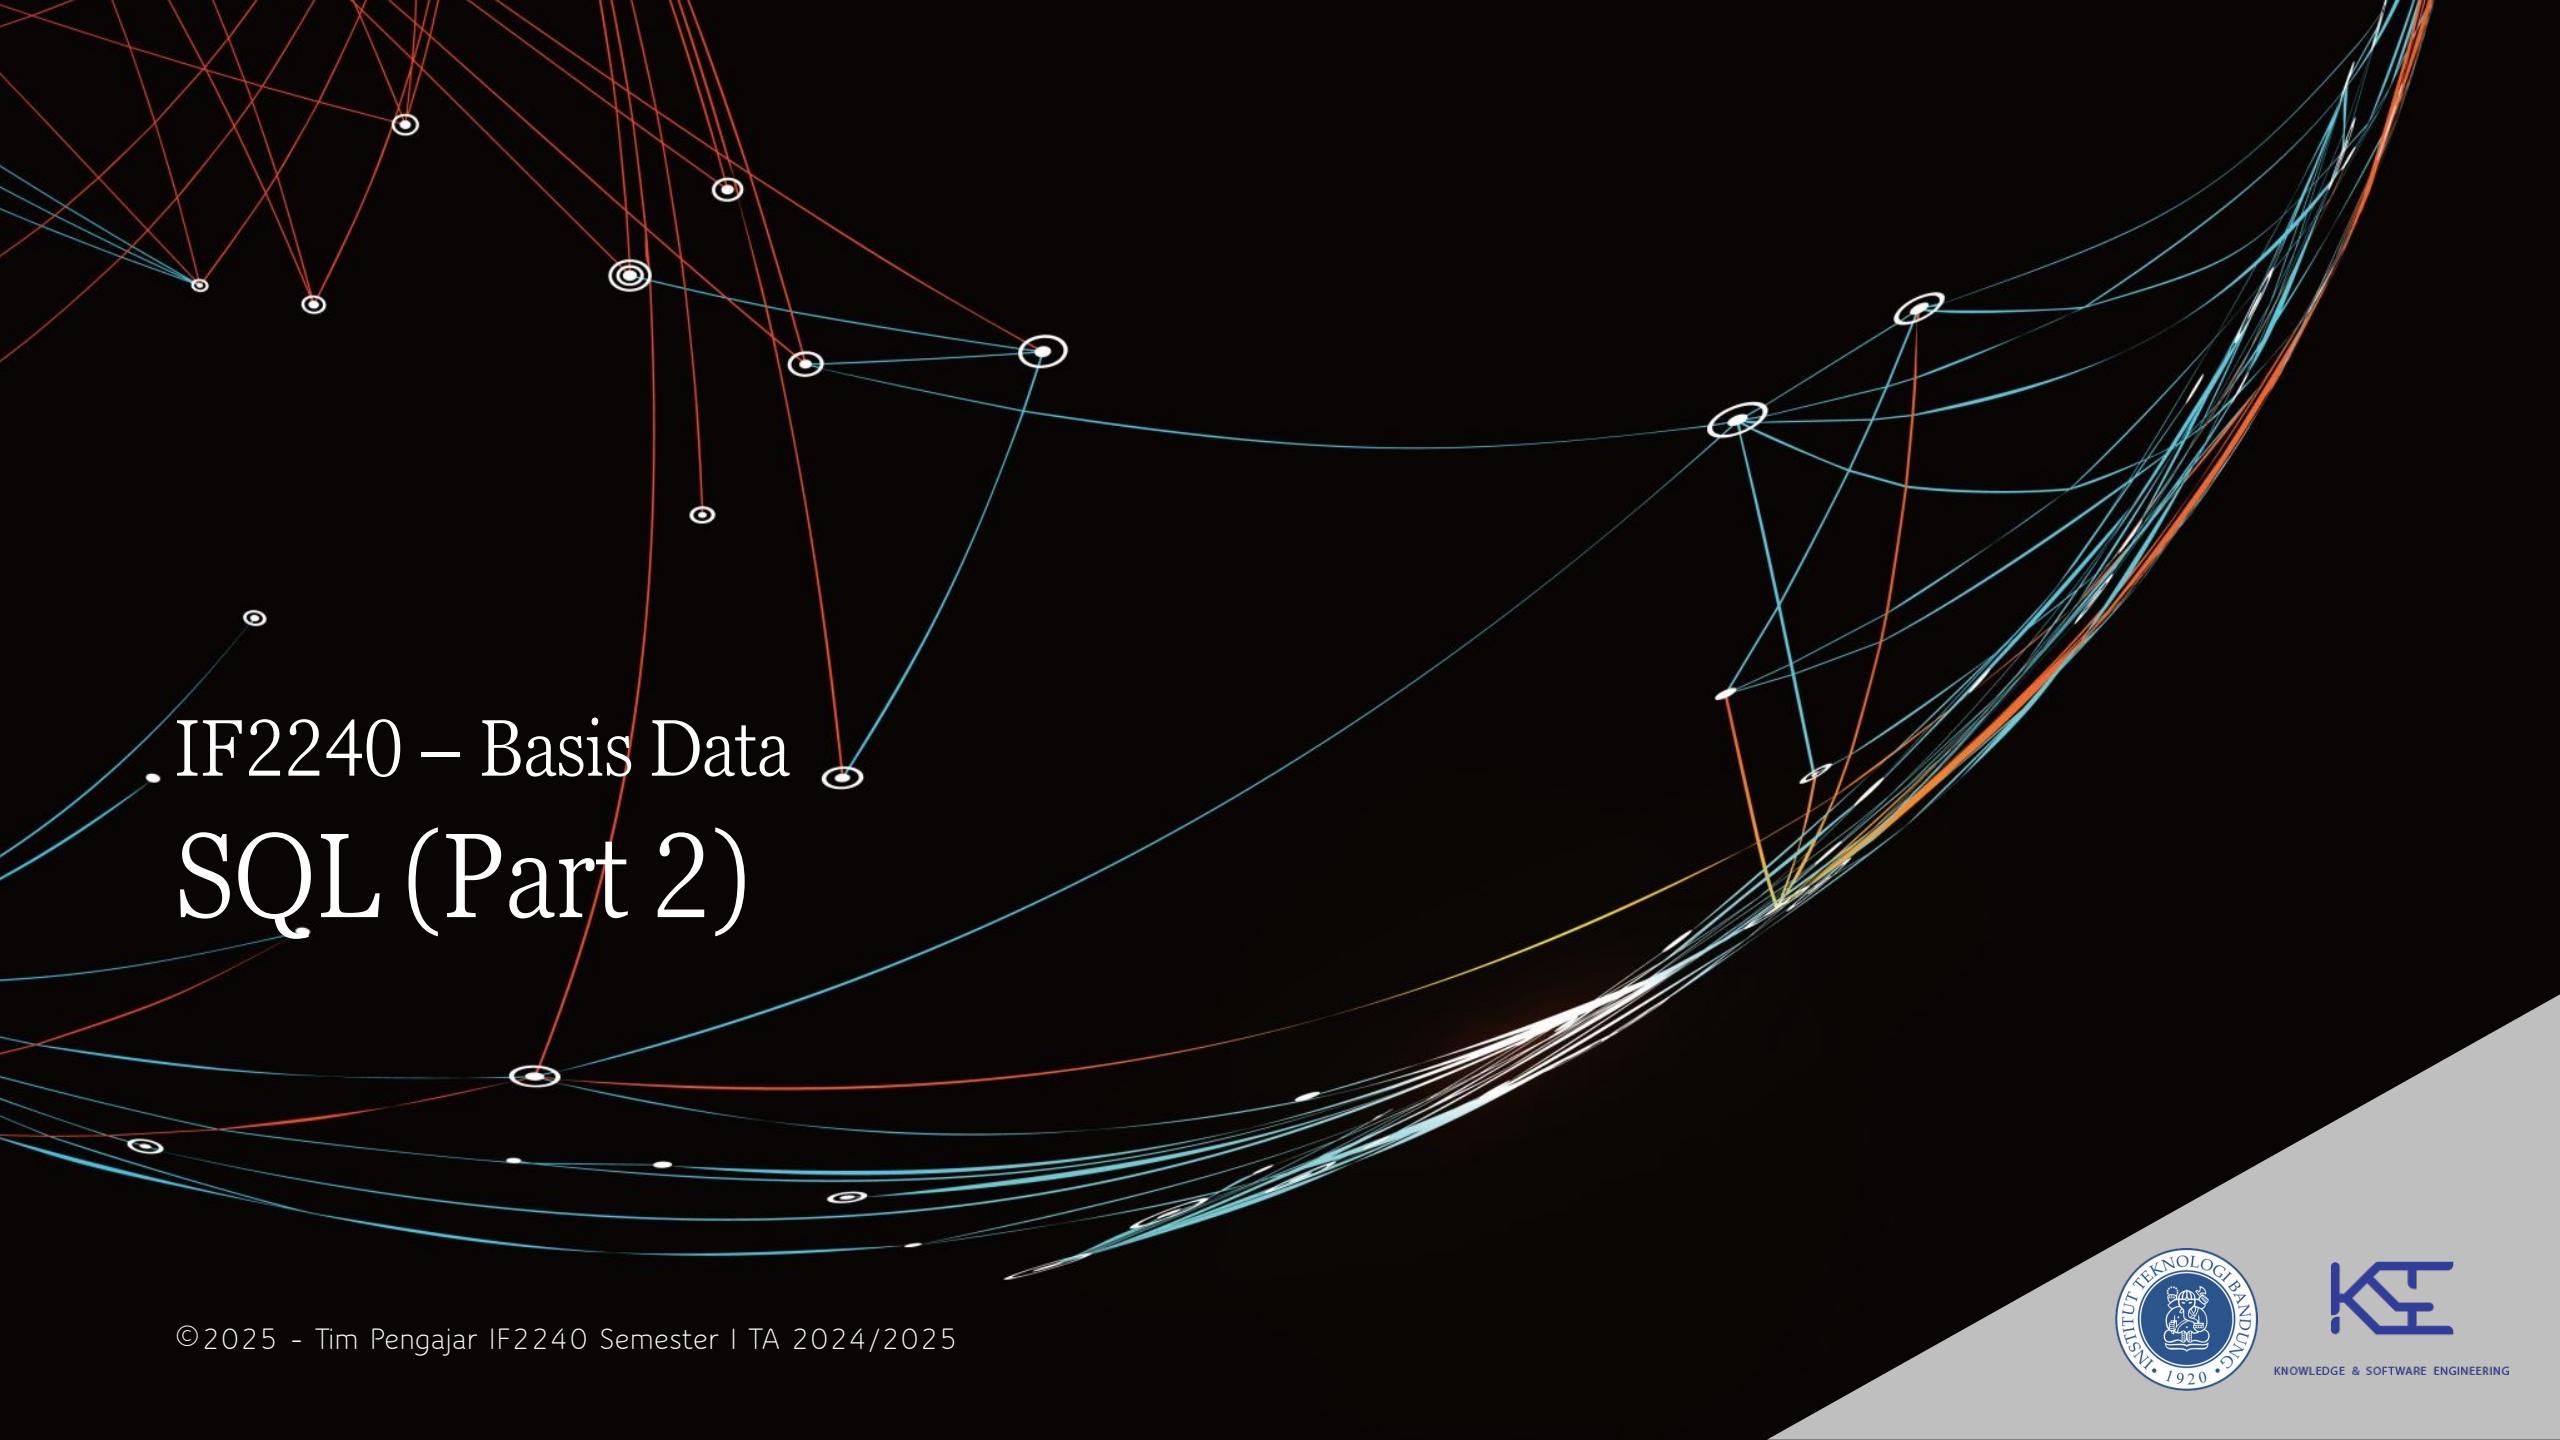

The predicate in a **where** clause can involve Boolean operations (**and**, **or**, **not**); thus the definitions of the Boolean operations need to be extended to deal with the value **unknown**.

- **and** : $(\text{true and unknown}) = \text{unknown}$,
 $(\text{false and unknown}) = \text{false}$,
 $(\text{unknown and unknown}) = \text{unknown}$
- **or**: $(\text{unknown or true}) = \text{true}$,
 $(\text{unknown or false}) = \text{unknown}$
 $(\text{unknown or unknown}) = \text{unknown}$

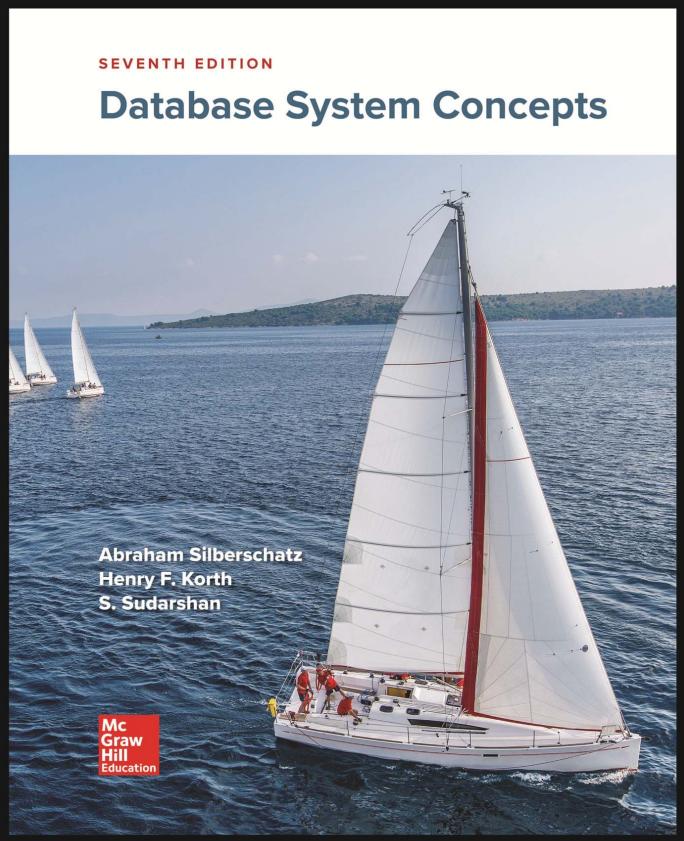

Result of **where** clause predicate is treated as *false* if it evaluates to *unknown*

Latihan-1

1. Tampilkan data ID dan nama student yang berasal dari departemen “Comp. Sci.”.
2. Tampilkan data instruktur dari departemen “Comp. Sci” yang memiliki gaji antara 7.000.000 hingga 12.000.000 terurut mengecil berdasarkan gaji.
3. Tampilkan data student dengan nama berawalan “Budi” dan terdiri dari sekurang-kurangnya 2 kata.
4. Tampilkan daftar mata kuliah (kode, nama, sks) yang diambil oleh student dengan ID “13521400” pada semester 2 tahun 2022.
5. Tampilkan daftar seluruh kelas yang ditawarkan oleh departemen “Comp. Sci.” pada semester 2 tahun 2022. Informasi yang ingin ditampilkan meliputi kode kuliah, nama, jumlah sks, nomor kelas (sec_id), serta nama dari instruktur kelas tersebut. Daftar terurut berdasarkan kode kuliah dan nomor kelas.

- Chapter 3 : Introduction to SQL

Aggregate Functions

These functions operate on the multiset of values of a column of a relation, and return a value

avg: average value

min: minimum value

max: maximum value

sum: sum of values

count: number of values

Aggregate Functions Examples

Find the average salary of instructors in the Computer Science department

- ```
select avg (salary)
from instructor
where dept_name= 'Comp. Sci.';
```

Find the total number of instructors who teach a course in the Spring 2018 semester

- ```
select count (distinct ID)
from teaches
where semester = 'Spring' and year = 2018;
```

Find the number of tuples in the *course* relation

- ```
select count (*)
from course;
```

KNOWLEDGE & SOFTWARE ENGINEERING

# Aggregate Functions – Group By

Group By: Group tuple that have the same values into summary rows

- Often used with aggregate functions

Find the average salary of instructors in each department

- ```
select dept_name,
       avg (salary) as avg_salary
  from instructor
 group by dept_name;
```

ID	name	dept_name	salary
76766	Crick	Biology	72000
45565	Katz	Comp. Sci.	75000
10101	Srinivasan	Comp. Sci.	65000
83821	Brandt	Comp. Sci.	92000
98345	Kim	Elec. Eng.	80000
12121	Wu	Finance	90000
76543	Singh	Finance	80000
32343	El Said	History	60000
58583	Califieri	History	62000
15151	Mozart	Music	40000
33456	Gold	Physics	87000
22222	Einstein	Physics	95000

dept_name	avg_salary
Biology	72000
Comp. Sci.	77333
Elec. Eng.	80000
Finance	85000
History	61000
Music	40000
Physics	91000

Aggregation (Cont.)

Attributes in **select** clause outside of aggregate functions must appear in **group by** list

- /* erroneous query */

```
select dept_name, ID, avg (salary)
from instructor
group by dept_name;
```

Aggregate Functions – Having Clause

HAVING clause was added to SQL because the WHERE keyword could not be used with aggregate functions

Find the names and average salaries of all departments whose average salary is greater than 42000

```
select dept_name, avg (salary) as avg_salary
from instructor
group by dept_name
having avg (salary) > 42000;
```

Note: predicates in the **having** clause are applied after the formation of groups whereas predicates in the **where** clause are applied before forming groups

KNOWLEDGE & SOFTWARE ENGINEERING

How About Some More Queries?

6. Find the highest salary earned by instructors from Comp. Sci. Department.
7. Find the enrollment of each section that was offered in Autumn 2009.
8. Find all departments with more than 1000 student enrollments, together with the number of students for each of them. The list should be ordered by dept_name
9. Find all instructors earning the highest salary (there may be more than one with the same salary)

Joined Relations

Join operations take two relations and return as a result another relation.

A join operation is a Cartesian product which requires that tuples in the two relations match (under some condition). It also specifies the attributes that are present in the result of the join

The join operations are typically used as subquery expressions in the **from** clause

Three types of joins:

- Natural join
- Inner join
- Outer join

Natural Join in SQL

Natural join matches tuples with the same values for all common attributes, and retains only one copy of each common column.

List the names of instructors along with the course ID of the courses that they taught

- `select name, course_id
from students, takes
where student.ID = takes.ID;`

Same query in SQL with “natural join” construct

- `select name, course_id
from student natural join takes;`

Natural Join in SQL (Cont.)

The **from** clause can have multiple relations combined using natural join:

```
select A1, A2, .. An
  from r1 natural join r2 natural join .. natural join rn
    where P ;
```

Student Relation

98988	Tanaka	Biology	120	BIO-301	1	Summer	2018	<i>null</i>

Dangerous in Natural Join

Beware of unrelated attributes with same name which get equated incorrectly

Example -- List the names of students instructors along with the titles of courses that they have taken

- Correct version

```
select name, title  
from student natural join takes, course  
where takes.course_id = course.course_id;
```

- Incorrect version

```
select name, title  
from student natural join takes natural join course;
```

- This query omits all (student name, course title) pairs where the student takes a course in a department other than the student's own department.
- The correct version (above), correctly outputs such pairs.

Outer Join

An extension of the join operation that avoids loss of information.

Computes the join and then adds tuples from one relation that does not match tuples in the other relation to the result of the join.

Uses *null* values.

Three forms of outer join:

- left outer join
- right outer join
- full outer join

Outer Join Examples

Relation *course*

course_id	title	dept_name	credits
BIO-301	Genetics	Biology	4
CS-190	Game Design	Comp. Sci.	4
CS-315	Robotics	Comp. Sci.	3

Relation *prereq*

course_id	prereq_id
BIO-301	BIO-101
CS-190	CS-101
CS-347	CS-101

Observe that

course information is missing CS-347

prereq information is missing CS-315

Left Outer Join

course natural left outer join prereq

<i>course_id</i>	<i>title</i>	<i>dept_name</i>	<i>credits</i>	<i>prereq_id</i>
BIO-301	Genetics	Biology	4	BIO-101
CS-190	Game Design	Comp. Sci.	4	CS-101
CS-315	Robotics	Comp. Sci.	3	<i>null</i>

In relational algebra: $course \bowtie prereq$

Right Outer Join

course natural right outer join prereq

<i>course_id</i>	<i>title</i>	<i>dept_name</i>	<i>credits</i>	<i>prereq_id</i>
BIO-301	Genetics	Biology	4	BIO-101
CS-190	Game Design	Comp. Sci.	4	CS-101
CS-347	<i>null</i>	<i>null</i>	<i>null</i>	CS-101

In relational algebra: $course \bowtie prereq$

Full Outer Join

course natural full outer join prereq

<i>course_id</i>	<i>title</i>	<i>dept_name</i>	<i>credits</i>	<i>prereq_id</i>
BIO-301	Genetics	Biology	4	BIO-101
CS-190	Game Design	Comp. Sci.	4	CS-101
CS-315	Robotics	Comp. Sci.	3	<i>null</i>
CS-347	<i>null</i>	<i>null</i>	<i>null</i>	CS-101

In relational algebra: $course \bowtie prereq$

Joined Types and Conditions

Join operations take two relations and return as a result another relation.

These additional operations are typically used as subquery expressions in the **from** clause

Join condition – defines which tuples in the two relations match.

- natural
- on <predicate>
- using (A_1, A_2, \dots, A_n)

Join type – defines how tuples in each relation that do not match any tuple in the other relation (based on the join condition) are treated.

- inner join
- left outer join
- right outer join
- full outer join

Joined Relations – Examples

course natural right outer join prereq

<i>course_id</i>	<i>title</i>	<i>dept_name</i>	<i>credits</i>	<i>prereq_id</i>
BIO-301	Genetics	Biology	4	BIO-101
CS-190	Game Design	Comp. Sci.	4	CS-101
CS-347	<i>null</i>	<i>null</i>	<i>null</i>	CS-101

course full outer join prereq using (course_id)

<i>course_id</i>	<i>title</i>	<i>dept_name</i>	<i>credits</i>	<i>prereq_id</i>
BIO-301	Genetics	Biology	4	BIO-101
CS-190	Game Design	Comp. Sci.	4	CS-101
CS-315	Robotics	Comp. Sci.	3	<i>null</i>
CS-347	<i>null</i>	<i>null</i>	<i>null</i>	CS-101

Joined Relations – Examples

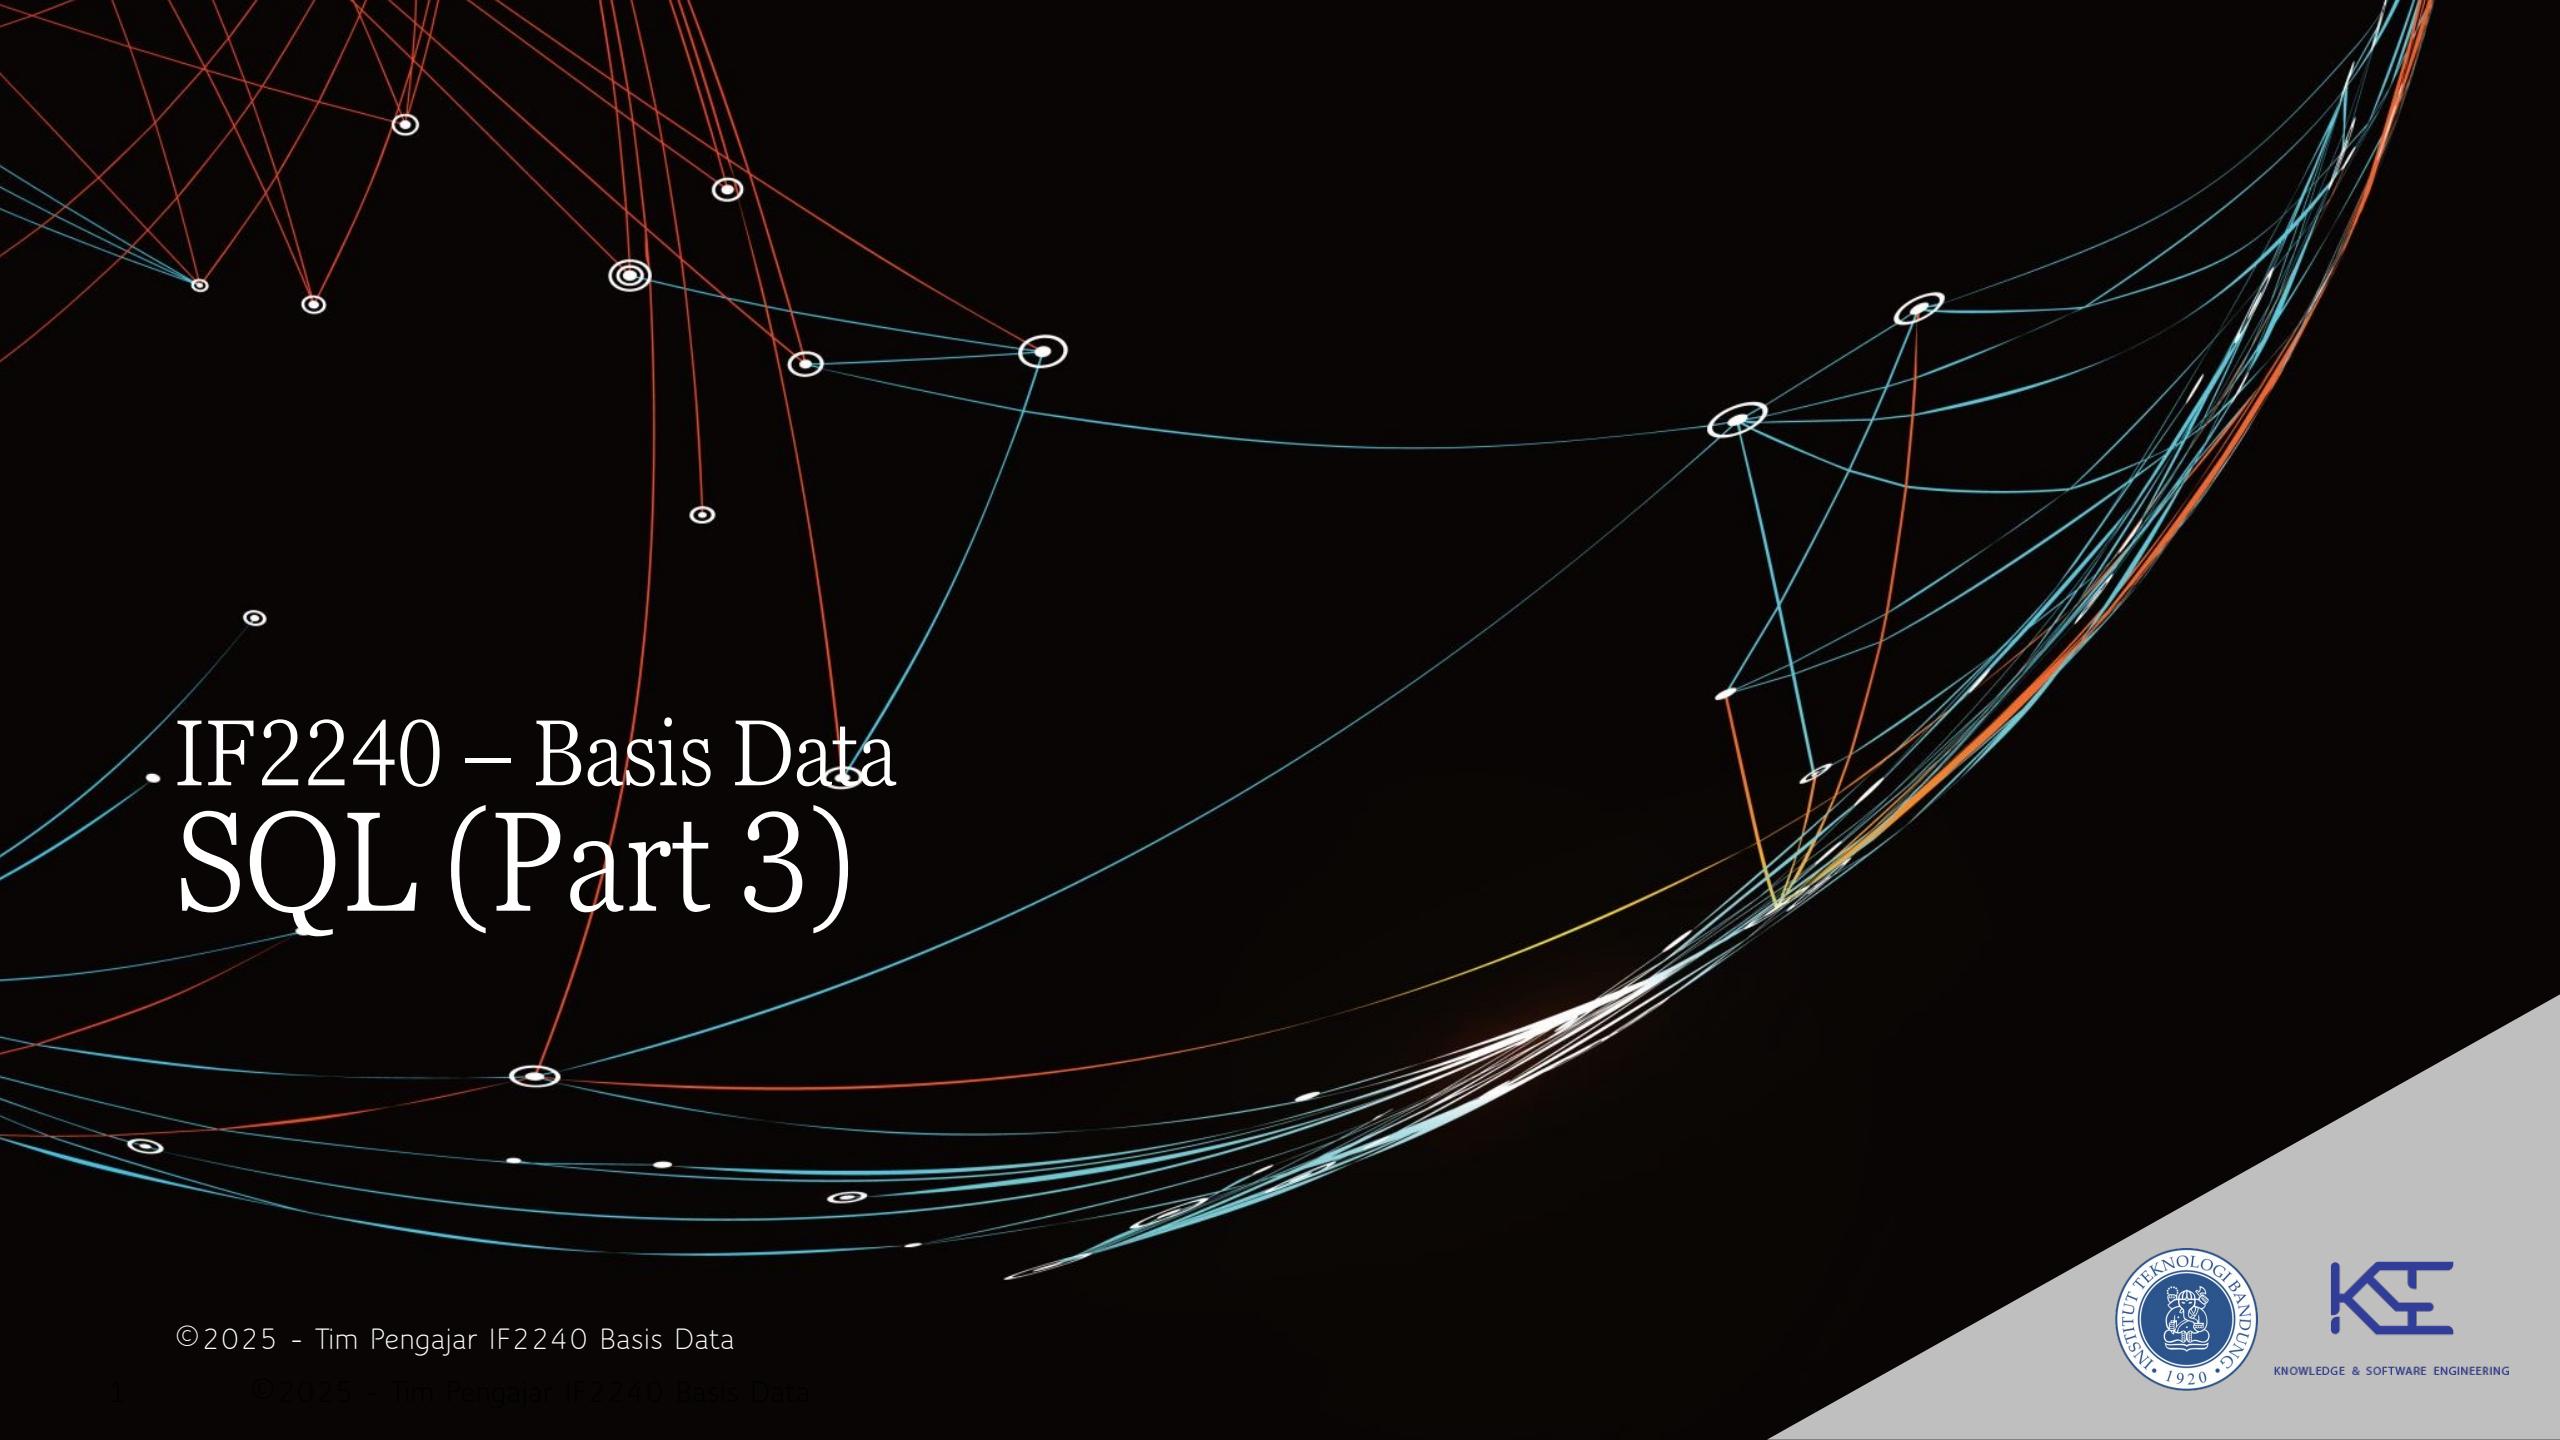

```
course inner join prereq on  
course.course_id = prereq.course_id
```

course_id	title	dept_name	credits	prereq_id	course_id
BIO-301	Genetics	Biology	4	BIO-101	BIO-301
CS-190	Game Design	Comp. Sci.	4	CS-101	CS-190

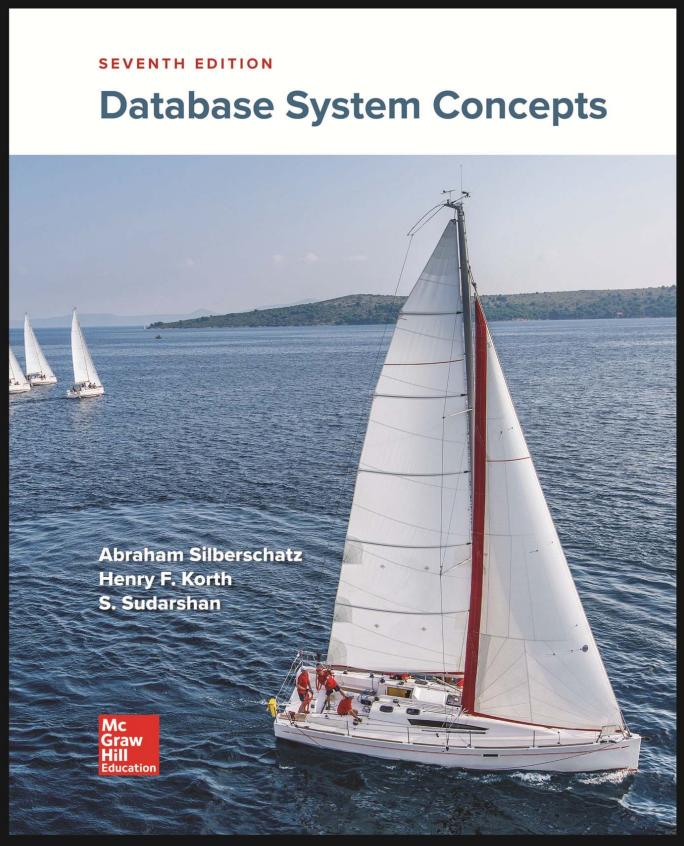

What is the difference between the above, and a natural join?

```
course left outer join prereq on  
course.course_id = prereq.course_id
```

course_id	title	dept_name	credits	prereq_id	course_id
BIO-301	Genetics	Biology	4	BIO-101	BIO-301
CS-190	Game Design	Comp. Sci.	4	CS-101	CS-190
CS-315	Robotics	Comp. Sci.	3	null	null

- Chapter 4 : Intermediate SQL

KNOWLEDGE & SOFTWARE ENGINEERING

Schema Diagram

Nested Subqueries

SQL provides a mechanism for the nesting of subqueries. A **subquery** is a **select-from-where** expression that is nested within another query.

The nesting can be done in the following SQL query

```
select A1, A2, ..., An
from r1, r2, ..., rm
where P
```

as follows:

- **Where clause:** P can be replaced with an expression of the form:
$$B \langle\text{operation}\rangle (\text{subquery})$$

 B is an attribute and $\langle\text{operation}\rangle$ to be defined later.
- **From clause:** r_i can be replaced by any valid subquery
- **Select clause:**
 A_i can be replaced by a subquery that generates a single value.

Nested Query in Where Clause

- Set Membership (**IN**): to check whether an attribute value is a member of the result set produced by a subquery.
- Set Comparison (**<relational operator> SOME/ALL**): to evaluate whether an attribute value satisfies the **<relational operator>** condition against some or all tuples in the subquery result.
- Test of Empty Relation (**EXISTS**): to determine whether a subquery returns any tuples (i.e., whether the subquery produces a result).
- Test for Absence of Duplicates (**UNIQUE**): to check whether the tuples in the subquery result are unique (i.e., no duplicate values exist).

Set Membership

Find courses offered in Fall 2017 and in Spring 2018

```
select distinct course_id  
from section  
where semester = 'Fall' and year= 2017 and  
course_id in (select course_id  
from section  
where semester = 'Spring' and year= 2018);
```

Find courses offered in Fall 2017 but not in Spring 2018

```
select distinct course_id  
from section  
where semester = 'Fall' and year= 2017 and  
course_id not in (select course_id  
from section  
where semester = 'Spring' and year= 2018);
```

KNOWLEDGE & SOFTWARE ENGINEERING

Set Membership (Cont.)

Name all instructors whose name is neither "Mozart" nor Einstein"

```
select distinct name  
from instructor  
where name not in ('Mozart', 'Einstein')
```

Find the total number of (distinct) students who have taken course sections taught by the instructor with *ID* 10101

```
select count (distinct ID)  
from takes  
where (course_id, sec_id, semester, year) in  
      (select course_id, sec_id, semester, year  
       from teaches  
       where teaches.ID= 10101);
```

Note: Above query can be written in a much simpler manner.

The formulation above is simply to illustrate SQL features

KNOWLEDGE & SOFTWARE ENGINEERING

Set Comparison – “some” Clause

Find names of instructors with salary greater than that of some (at least one) instructor in the Biology department.

```
select distinct T.name
from instructor as T, instructor as S
where T.salary > S.salary and S.dept name = 'Biology';
```

Same query using `> some` clause

```
select name
from instructor
where salary > some (select salary
              from instructor
              where dept name = 'Biology');
```

KNOWLEDGE & SOFTWARE ENGINEERING

Definition of “some” Clause

$F <\text{comp}> \text{some } r \Leftrightarrow \exists t \in r \text{ such that } (F <\text{comp}> t)$

Where comp can be: $<$, \leq , $>$, $=$, \neq

$(5 < \text{some} \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline 6 \\ \hline \end{array}) = \text{true}$ (read: 5 < some tuple in the relation)

$(5 < \text{some} \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline \end{array}) = \text{false}$

$(5 = \text{some} \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline \end{array}) = \text{true}$

$(5 \neq \text{some} \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline \end{array}) = \text{true}$ (since $0 \neq 5$)

$(= \text{some}) \equiv \text{in}$

However, $(\neq \text{some}) \equiv \text{not in}$

Set Comparison – “all” Clause

Find the names of all instructors whose salary is greater than the salary of all instructors in the Biology department.

```
select name  
from instructor  
where salary > all (select salary  
                 from instructor  
                 where dept name = 'Biology');
```

Definition of “all” Clause

$$F \langle \text{comp} \rangle \text{ all } r \Leftrightarrow \forall t \in r (F \langle \text{comp} \rangle t)$$

$(5 < \text{all } \begin{array}{|c|}\hline 0 \\ \hline 5 \\ \hline 6 \\ \hline \end{array}) = \text{false}$

$(5 < \text{all } \begin{array}{|c|}\hline 6 \\ \hline 10 \\ \hline \end{array}) = \text{true}$

$(5 = \text{all } \begin{array}{|c|}\hline 4 \\ \hline 5 \\ \hline \end{array}) = \text{false}$

$(5 \neq \text{all } \begin{array}{|c|}\hline 4 \\ \hline 6 \\ \hline \end{array}) = \text{true}$ (since $5 \neq 4$ and $5 \neq 6$)

$(\neq \text{all}) \equiv \text{not in}$
However, $(= \text{all}) \not\equiv \text{in}$

Test for Empty Relations

The **exists** construct returns the value **true** if the argument subquery is nonempty.

$$\text{exists } r \Leftrightarrow r \neq \emptyset$$

$$\text{not exists } r \Leftrightarrow r = \emptyset$$

Use of “exists” Clause

Yet another way of specifying the query “Find all courses taught in both the Fall 2017 semester and in the Spring 2018 semester”

```
select course_id  
from section as S  
where semester = 'Fall' and year = 2017 and  
exists (select *  
        from section as T  
        where semester = 'Spring' and year= 2018  
        and S.course_id = T.course_id);
```

Correlation name – variable S in the outer query

Correlated subquery – the inner query

Use of “not exists” Clause

Find all students who have taken all courses offered in the Biology department.

```
select distinct S.ID, S.name  
from student as S  
where not exists ((select course_id  
         from course  
         where dept_name = 'Biology')  
except  
    (select T.course_id  
      from takes as T  
      where S.ID = T.ID));
```

- First nested query lists all courses offered in Biology
- Second nested query lists all courses a particular student took

Note that $X - Y = \emptyset \Leftrightarrow X \subseteq Y$

Note: Cannot write this query using = all and its variants

Test for Absence of Duplicate Tuples

The **unique** construct tests whether a subquery has any duplicate tuples in its result.

The **unique** construct evaluates to “true” if a given subquery contains no duplicates .

Find all courses that were offered at most once in 2017

```
select T.course_id  
from course as T  
where unique ( select R.course_id  
                from section as R  
                where T.course_id= R.course_id  
                  and R.year = 2017);
```

Subqueries in the From Clause

SQL allows a subquery expression to be used in the **from** clause

Find the average instructors' salaries of those departments where the average salary is greater than \$42,000."

```
select dept_name, avg_salary
from ( select dept_name, avg (salary) as avg_salary
       from instructor
       group by dept_name)
      where avg_salary > 42000;
```

Note that we do not need to use the **having** clause

Another way to write above query

```
select dept_name, avg_salary
from ( select dept_name, avg (salary)
       from instructor
       group by dept_name)
      as dept_avg (dept_name, avg_salary)
      where avg_salary > 42000;
```

With Clause

The **with** clause provides a way of defining a temporary relation whose definition is available only to the query in which the **with** clause occurs.

Find all departments with the maximum budget

```
with max_budget (value) as
    (select max(budget)
     from department)
select department.name
from department, max_budget
where department.budget = max_budget.value;
```

Complex Queries using With Clause

Find all departments where the total salary is greater than the average of the total salary at all departments

```
with dept_total(dept_name, value) as
    (select dept_name, sum(salary)
     from instructor
     group by dept_name),
dept_total_avg(value) as
    (select avg(value)
     from dept_total)
select dept_name
from dept_total, dept_total_avg
where dept_total.value > dept_total_avg.value;
```

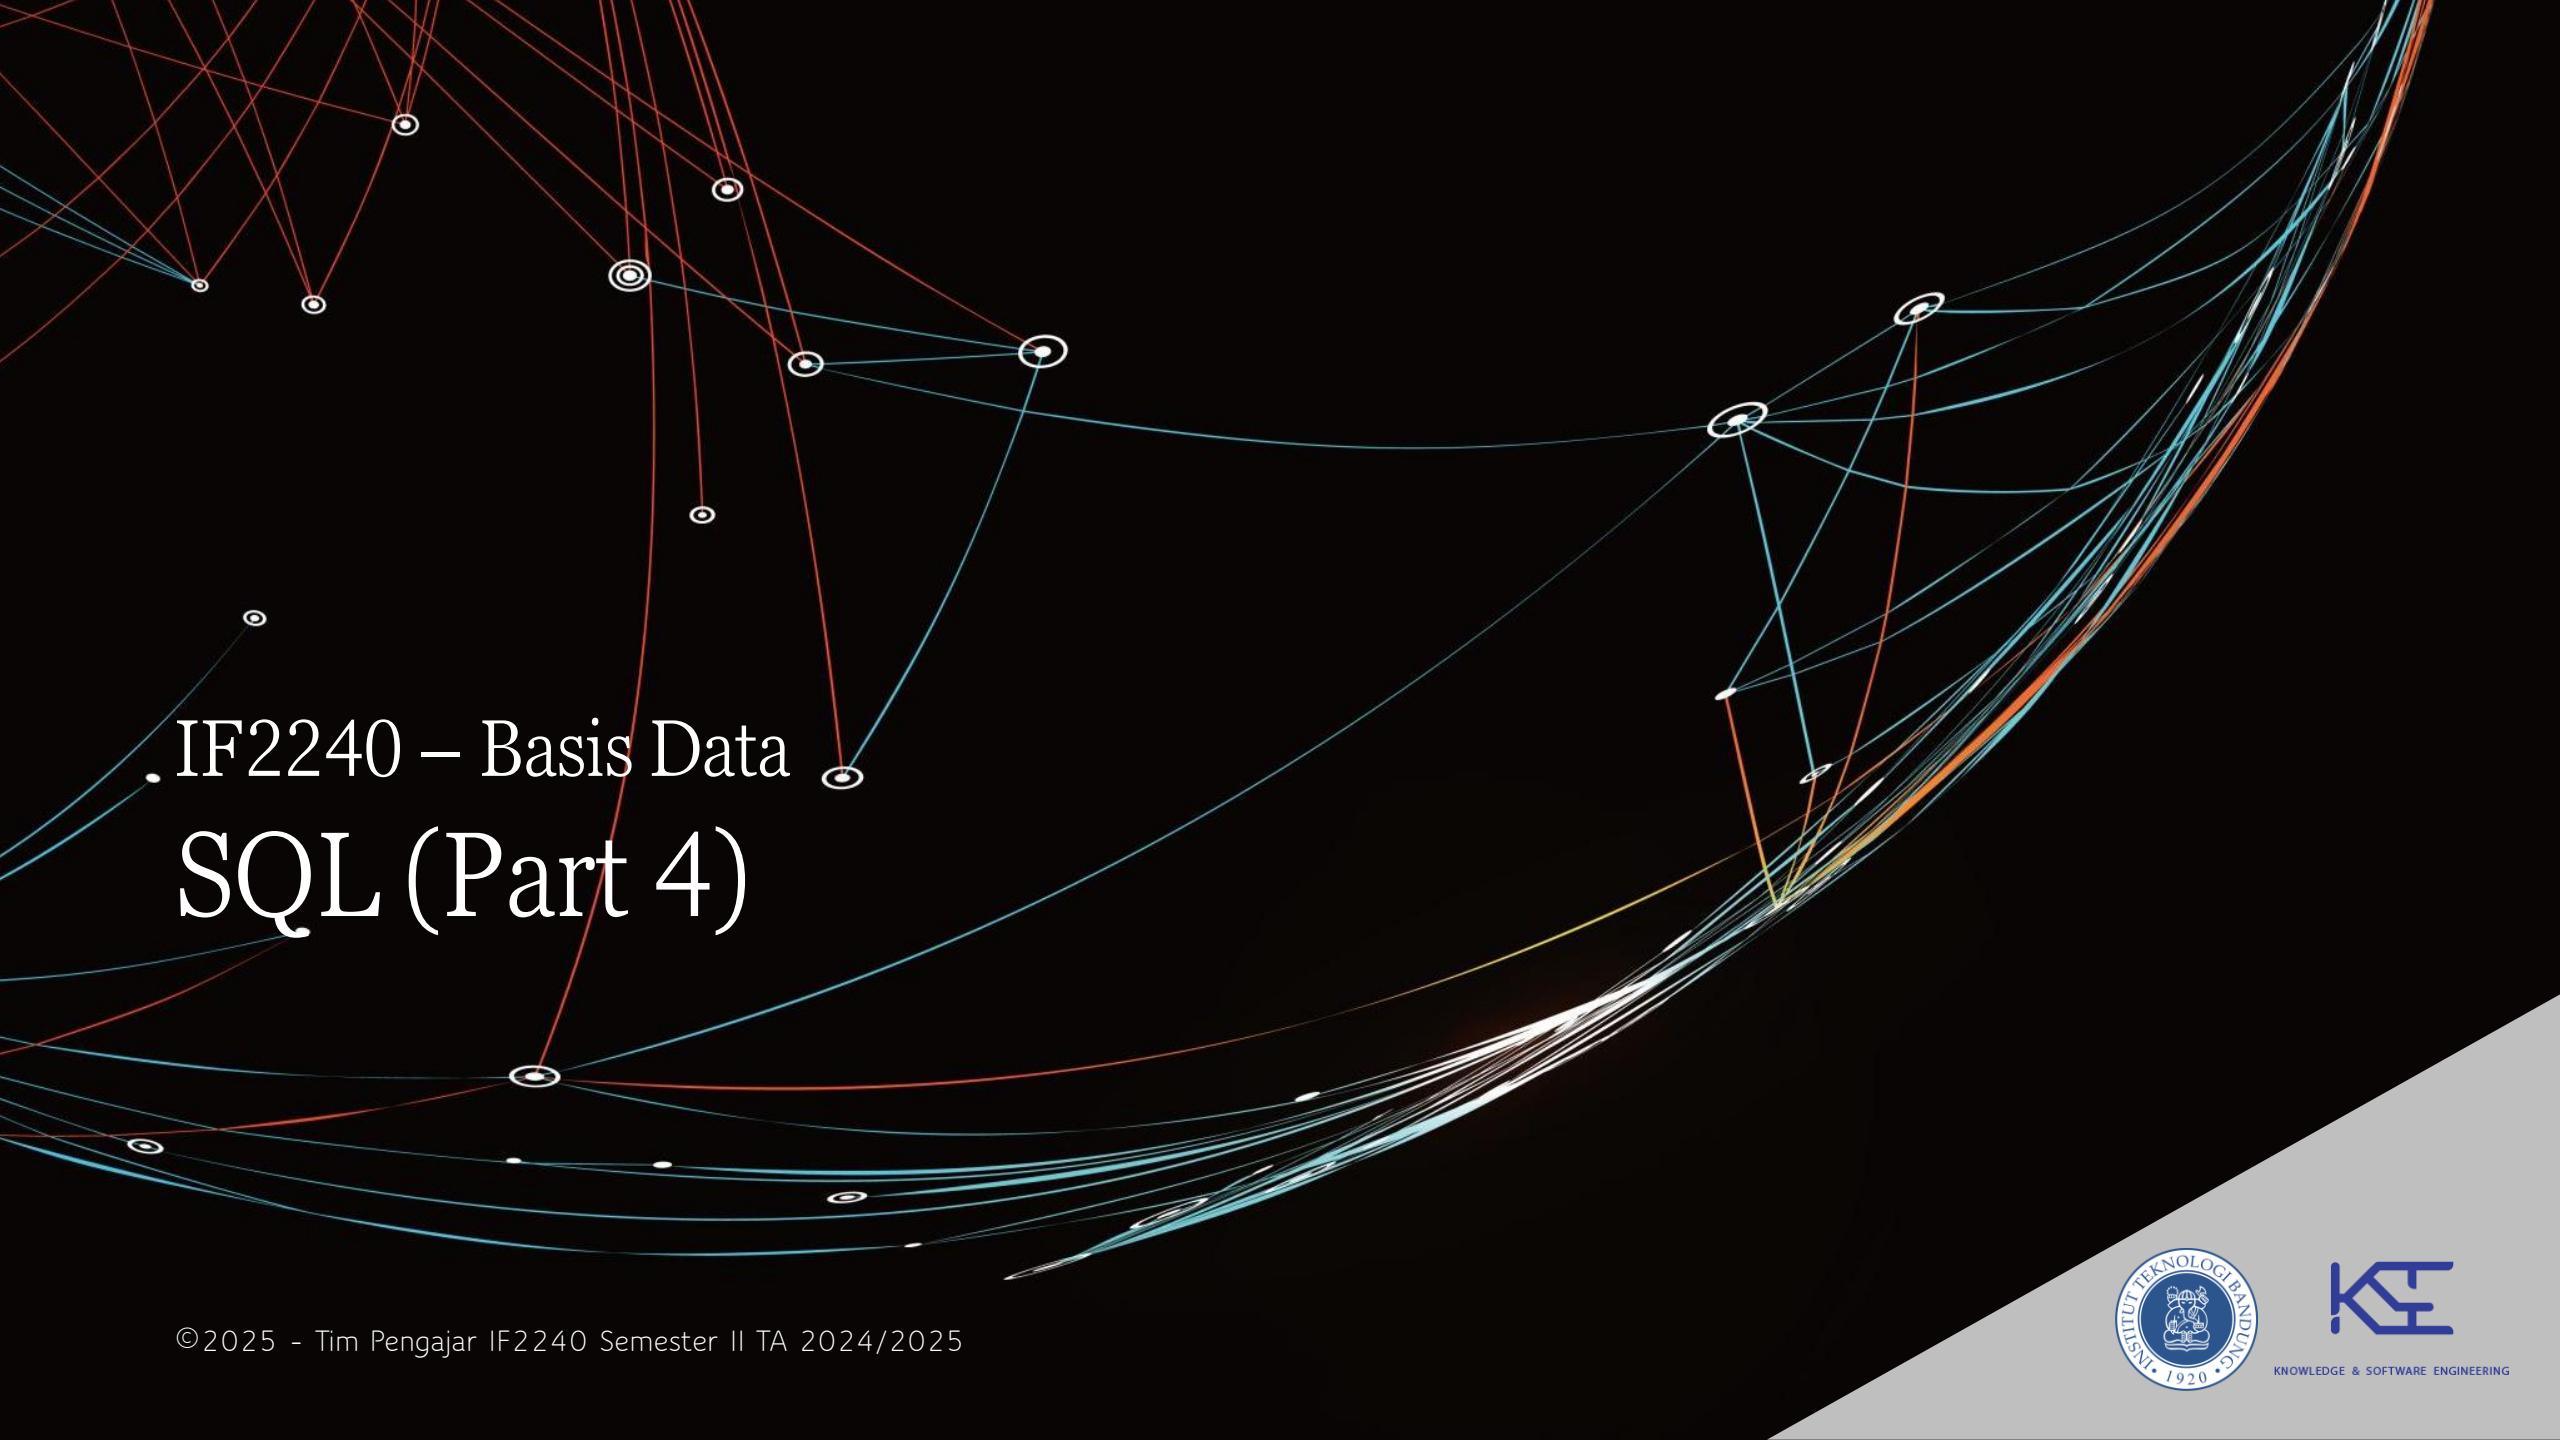

Scalar Subquery

Scalar subquery is one which is used where a single value is expected

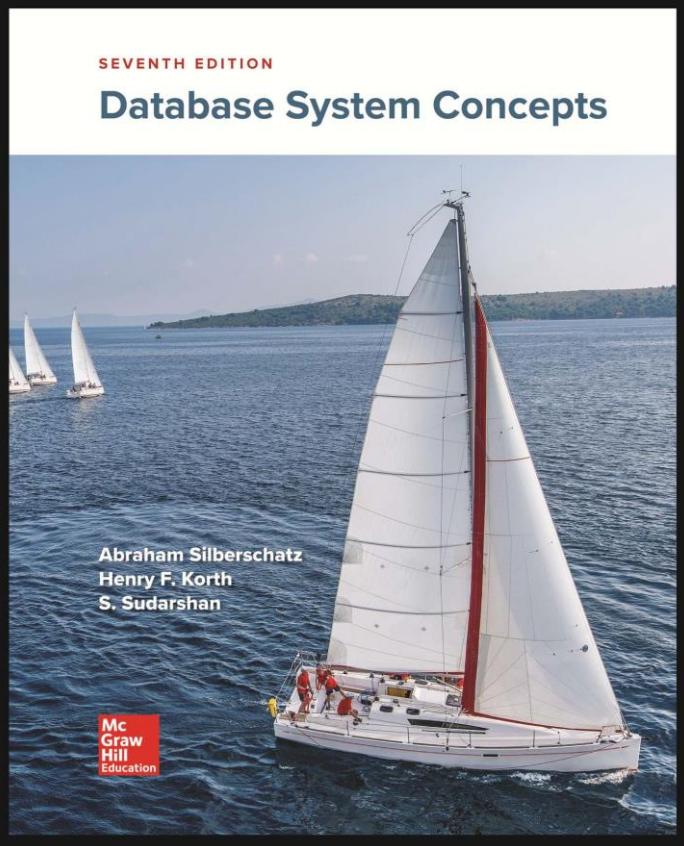

List all departments along with the number of instructors in each department

```
select dept_name,  
       ( select count(*)  
           from instructor  
         where department.dept_name = instructor.dept_name)  
      as num_instructors  
  from department;
```

Runtime error if subquery returns more than one result tuple

IF2240 – Basis Data SQL (Part 4)

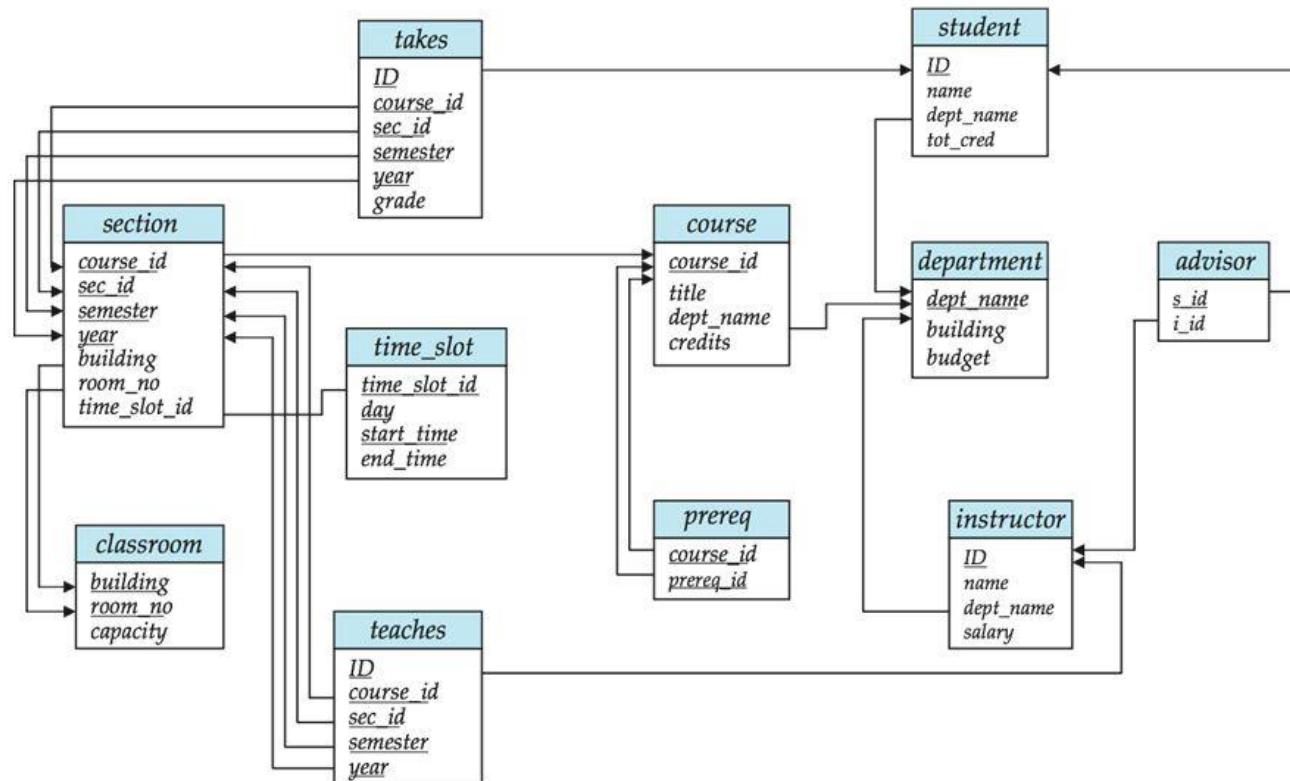

Sumber

Silberschatz, Korth, Sudarshan: "Database System Concepts", 7th Edition

- Chapter 3 : Introduction to SQL
- Chapter 4 : Intermediate SQL

Schema Diagram

View

Views

In some cases, it is not desirable for all users to see the entire logical model (that is, all the actual relations stored in the database.)

Consider a person who needs to know an instructor's name and department, but not the salary. This person should see a relation described, in SQL, by

```
select ID, name, dept_name  
from instructor
```

A **view** provides a mechanism to hide certain data from the view of certain users.

Any relation that is not of the conceptual model but is made visible to a user as a “virtual relation” is called a **view**.

KNOWLEDGE & SOFTWARE ENGINEERING

View Definition

A view is defined using the **create view** statement which has the form

```
create view v as < query expression >
```

where <query expression> is any legal SQL expression. The view name is represented by *v*.

Once a view is defined, the view name can be used to refer to the virtual relation that the view generates.

View definition is not the same as creating a new relation by evaluating the query expression

- Rather, a view definition causes the saving of an expression; the expression is substituted into queries using the view.

View Definition and Use

A view of instructors without their salary

```
create view faculty as  
    select ID, name, dept_name  
        from instructor
```

Find all instructors in the Biology department

```
select name  
from faculty  
where dept_name = 'Biology'
```

Create a view of department salary totals

```
create view departments_total_salary(dept_name, total_salary) as  
    select dept_name, sum (salary)  
        from instructor  
    group by dept_name;
```

KNOWLEDGE & SOFTWARE ENGINEERING

Views Defined Using Other Views (1/2)

One view may be used in the expression defining another view

A view relation v_1 is said to *depend directly* on a view relation v_2 if v_2 is used in the expression defining v_1

A view relation v_1 is said to *depend on* view relation v_2 if either v_1 depends directly to v_2 or there is a path of dependencies from v_1 to v_2

A view relation v is said to be *recursive* if it depends on itself.

Views Defined Using Other Views (2/2)

```
create view physics_fall_2017 as
    select course.course_id, sec_id, building, room_number
    from course, section
    where course.course_id = section.course_id
        and course.dept_name = 'Physics'
        and section.semester = 'Fall'
        and section.year = '2017';
```

```
create view physics_fall_2017_watson as
    select course_id, room_number
    from physics_fall_2017
    where building= 'Watson';
```

KNOWLEDGE & SOFTWARE ENGINEERING

Materialized Views

Certain database systems allow view relations to be physically stored.

- Physical copy created when the view is defined.
- Such views are called **Materialized view**:

If relations used in the query are updated, the materialized view result becomes out of date

- Need to **Maintain** the view, by updating the view whenever the underlying relations are updated.

Modification of the Database

Modification of the Database

Deletion of tuples from a given relation.

Insertion of new tuples into a given relation

Updating of values in some tuples of a given relation

Deletion

**delete from <table_name>
where <condition>;**

Delete all instructors

```
delete from instructor
```

Delete all instructors from the Finance department

```
delete from instructor  
where dept_name = 'Finance';
```

Delete all tuples in the instructor relation for those instructors associated with a department located in the Watson building.

**conditions involving tuples from other relations
are expressed using subquery.**

```
delete from instructor  
where dept_name in (select dept_name  
from department  
where building = 'Watson');
```

Deletion (Cont.)

Delete all instructors whose salary is less than the average salary of instructors

```
delete from instructor
where salary < (select avg (salary)
    from instructor);
```

- Problem: as we delete tuples from *instructor*, the average salary changes
- Solution used in SQL:
 1. First, compute **avg** (salary) and find all tuples to delete
 2. Next, delete all tuples found above (without recomputing **avg** or retesting the tuples)

Insertion

```
insert into <table_name> [(<attributes_list>)]  
values (<attributes_values>);
```

Add a new tuple to *course*

```
insert into course  
values ('CS-437', 'Database Systems', 'Comp. Sci.', 4);
```

or equivalently

```
insert into course (course_id, title, dept_name, credits)  
values ('CS-437', 'Database Systems', 'Comp. Sci.', 4);
```

Add a new tuple to *student* with *tot_creds* set to null

```
insert into student  
values ('3003', 'Green', 'Finance', null);
```

KNOWLEDGE & SOFTWARE ENGINEERING

Insertion (Cont.)

```
insert into <table_name> [(<attributes_list>)]  
<query>;
```

Make each student in the Music department who has earned more than 144 credit hours an instructor in the Music department with a salary of \$18,000.

```
insert into instructor  
select ID, name, dept_name, 18000  
from student  
where dept_name = 'Music' and total_cred > 144;
```

The select from where statement is evaluated fully before any of its results are inserted into the relation.

Otherwise queries like

```
insert into table1 select * from table1
```

would cause problem

Updates

```
update <table_name>
set <attribute_name> = <expression>
where <condition>;
```

Give a 5% salary raise to all instructors

```
update instructor
set salary = salary * 1.05
```

Give a 5% salary raise to those instructors who earn less than 70000

```
update instructor
set salary = salary * 1.05
where salary < 70000;
```

Give a 5% salary raise to instructors whose salary is less than average

```
update instructor
set salary = salary * 1.05
where salary < (select avg (salary)
from instructor);
```

KNOWLEDGE & SOFTWARE ENGINEERING

Updates (Cont.)

Increase salaries of instructors whose salary is over \$100,000 by 3%, and all others by a 5%

- Write two update statements:

```
update instructor  
    set salary = salary * 1.03  
    where salary > 100000;  
  
update instructor  
    set salary = salary * 1.05  
    where salary <= 100000;
```

- The order is important
- Can be done better using the case statement (next slide)

Case Statement for Conditional Updates

Same query as before but with case statement

```
update instructor  
set salary = case  
    when salary <= 100000 then salary * 1.05  
    else salary * 1.03  
end
```

Updates with Scalar Subqueries

Recompute and update tot_creds value for all students

```
update student S
set tot_cred = (select sum(credits)
                 from takes, course
                where takes.course_id = course.course_id and
                      S.ID= takes.ID and takes.grade <> 'F' and
                      takes.grade is not null);
```

Sets tot_creds to null for students who have not taken any course

Instead of sum(credits), use:

```
case
  when sum(credits) is not null then sum(credits)
  else 0
end
```

Update of a View

Add a new tuple to faculty view which we defined earlier

```
insert into faculty  
values ('30765', 'Green', 'Music');
```

This insertion must be represented by the insertion into the instructor relation

- Must have a value for salary.

Two approaches

- Reject the insert
- Insert the tuple

('30765', 'Green', 'Music', null)

into the instructor relation

Some Updates Cannot be Translated Uniquely

```
create view instructor_info as
    select ID, name, building
    from instructor, department
    where instructor.dept_name = department.dept_name;
```

```
insert into instructor_info
    values ('69987', 'White', 'Taylor');
```

Issues

- Which department, if multiple departments in Taylor?
- What if no department is in Taylor?

And Some Not at All

```
create view history_instructors as  
select *  
from instructor  
where dept_name= 'History';
```

What happens if we insert

```
('25566', 'Brown', 'Biology', 100000)
```

into history_instructors?

View Updates in SQL

Most SQL implementations allow updates only on simple views

- The from clause has only one database relation.
- The select clause contains only attribute names of the relation, and does not have any expressions, aggregates, or distinct specification.
- Any attribute not listed in the select clause can be set to null
- The query does not have a group by or having clause.

Data Definition Language

Data Definition Language

The SQL data-definition language (DDL) allows the specification of information about relations, including:

1. The schema for each relation.
2. The type of values associated with each attribute.
3. The Integrity constraints
4. The set of indices to be maintained for each relation.
5. Security and authorization information for each relation.
6. The physical storage structure of each relation on disk.

Domain Types in SQL (1/2)

char(n). Fixed length character string, with user-specified length n .

varchar(n). Variable length character strings, with user-specified maximum length n .

int. Integer (a finite subset of the integers that is machine-dependent).

smallint. Small integer (a machine-dependent subset of the integer domain type).

numeric(p,d). Fixed point number, with user-specified precision of p digits, with d digits to the right of decimal point. (ex., **numeric(3,1)**, allows 44.5 to be stored exactly, but not 444.5 or 0.32)

real, double precision. Floating point and double-precision floating point numbers, with machine-dependent precision.

float(n). Floating point number, with user-specified precision of at least n digits.

Domain Types in SQL (2/2)

date Dates, containing a (4 digit) year, month and date

- Example: `date '2005-7-27'`

time Time of day, in hours, minutes and seconds.

- Example: `time '09:00:30'` `time '09:00:30.75'`

timestamp date plus time of day

- Example: `timestamp '2005-7-27 09:00:30.75'`

interval: period of time

- Example: `interval '1' day`
- Subtracting a date/time/timestamp value from another gives an interval value
- Interval values can be added to date/time/timestamp values

Create Table Construct

An SQL relation is defined using the **create table** command:

```
create table r
  (A1 D1, A2 D2, ..., An Dn,
   (integrity-constraint1),
   ...
   (integrity-constraintk))
```

- *r* is the name of the relation
- each *A_i* is an attribute name in the schema of relation *r*
- *D_i* is the data type of values in the domain of attribute *A_i*

Example:

```
create table instructor (
  ID           char(5),
  name         varchar(20),
  dept_name   varchar(20),
  salary       numeric(8,2))
```

Integrity Constraints in Create Table

Types of integrity constraints

- primary key (A_1, \dots, A_n)
- foreign key (A_m, \dots, A_n) references r
- not null

SQL prevents any update to the database that violates an integrity constraint.

Example:

```
create table instructor (
    ID          char(5),
    name        varchar(20) not null,
    dept_name   varchar(20),
    salary      numeric(8,2),
    primary key (ID),
    foreign key (dept_name) references department);
```

And a Few More Relation Definitions

```
create table student (
    ID          varchar(5),
    name        varchar(20) not null,
    dept_name   varchar(20),
    tot_cred    numeric(3,0),
    primary key (ID),
    foreign key (dept_name) references department);
```

```
create table takes (
    ID          varchar(5),
    course_id   varchar(8),
    sec_id      varchar(8),
    semester    varchar(6),
    year        numeric(4,0),
    grade       varchar(2),
    primary key (ID, course_id, sec_id, semester, year) ,
    foreign key (ID) references student,
    foreign key (course_id, sec_id, semester, year) references section);
```

And more still

```
create table course (
    course_id      varchar(8),
    title          varchar(50),
    dept_name      varchar(20),
    credits         numeric(2,0),
    primary key (course_id),
    foreign key (dept_name) references department);
```

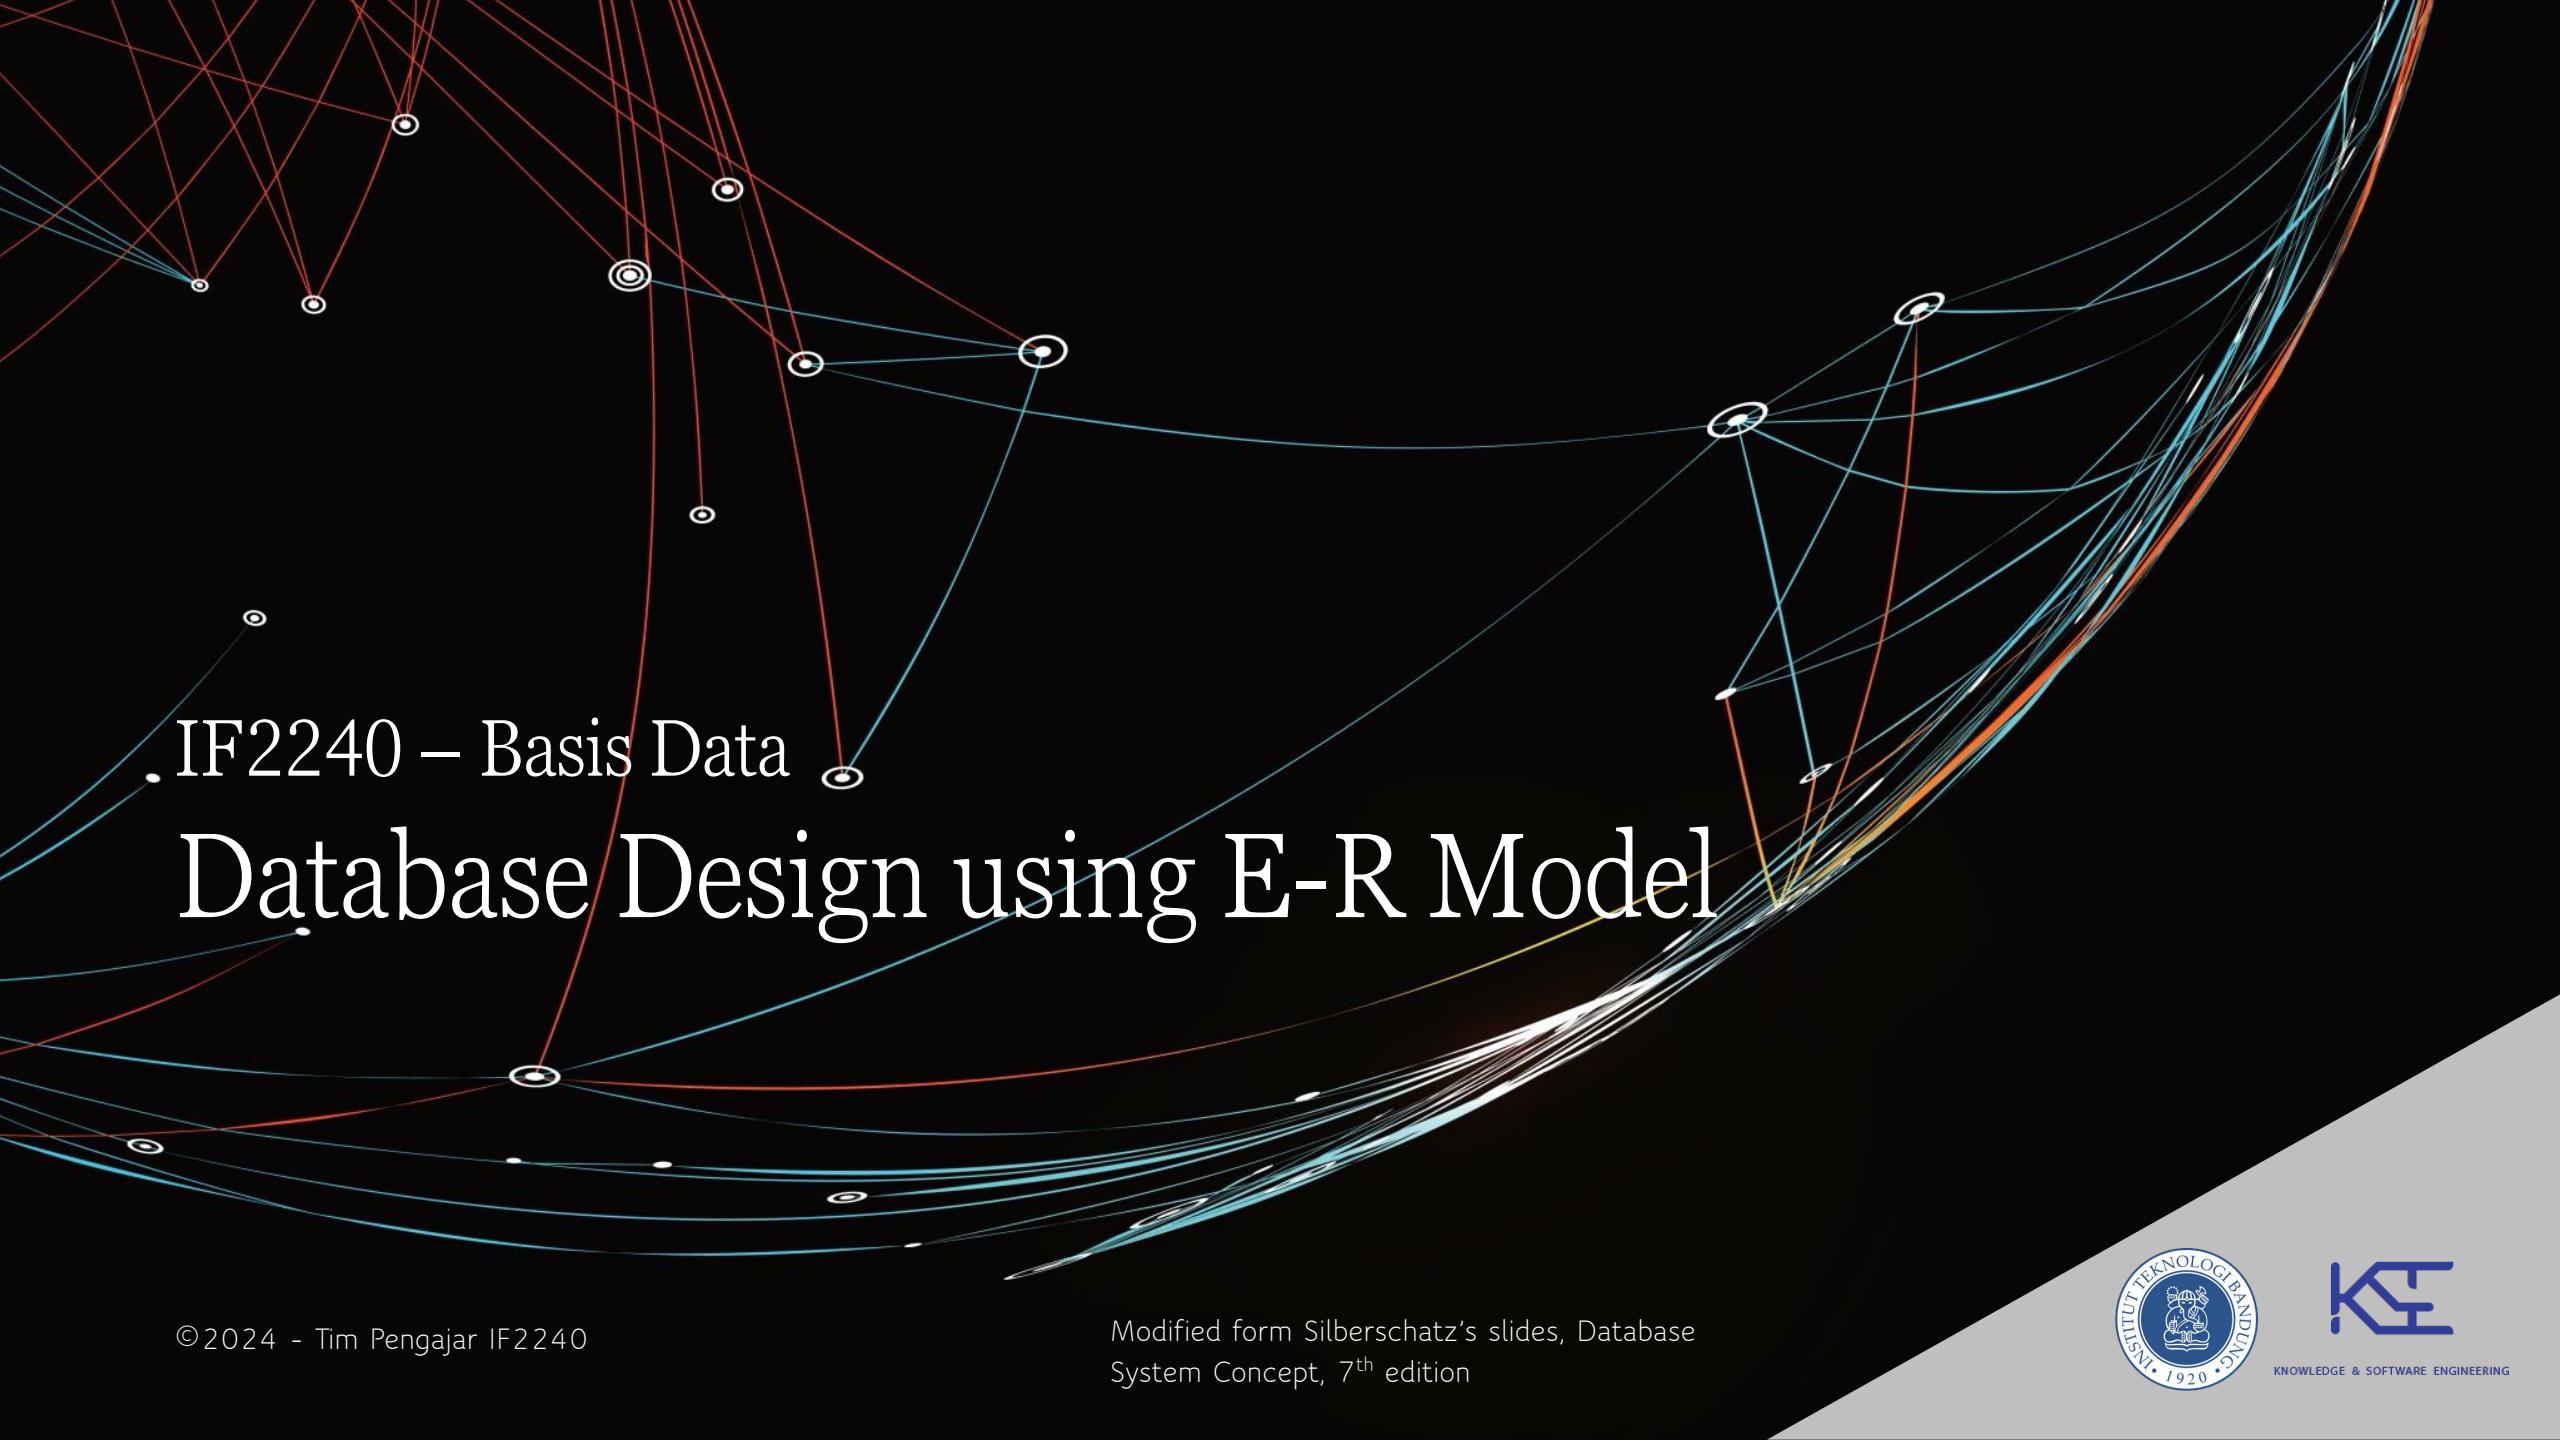

Updates to tables

Drop Table

- `drop table r`

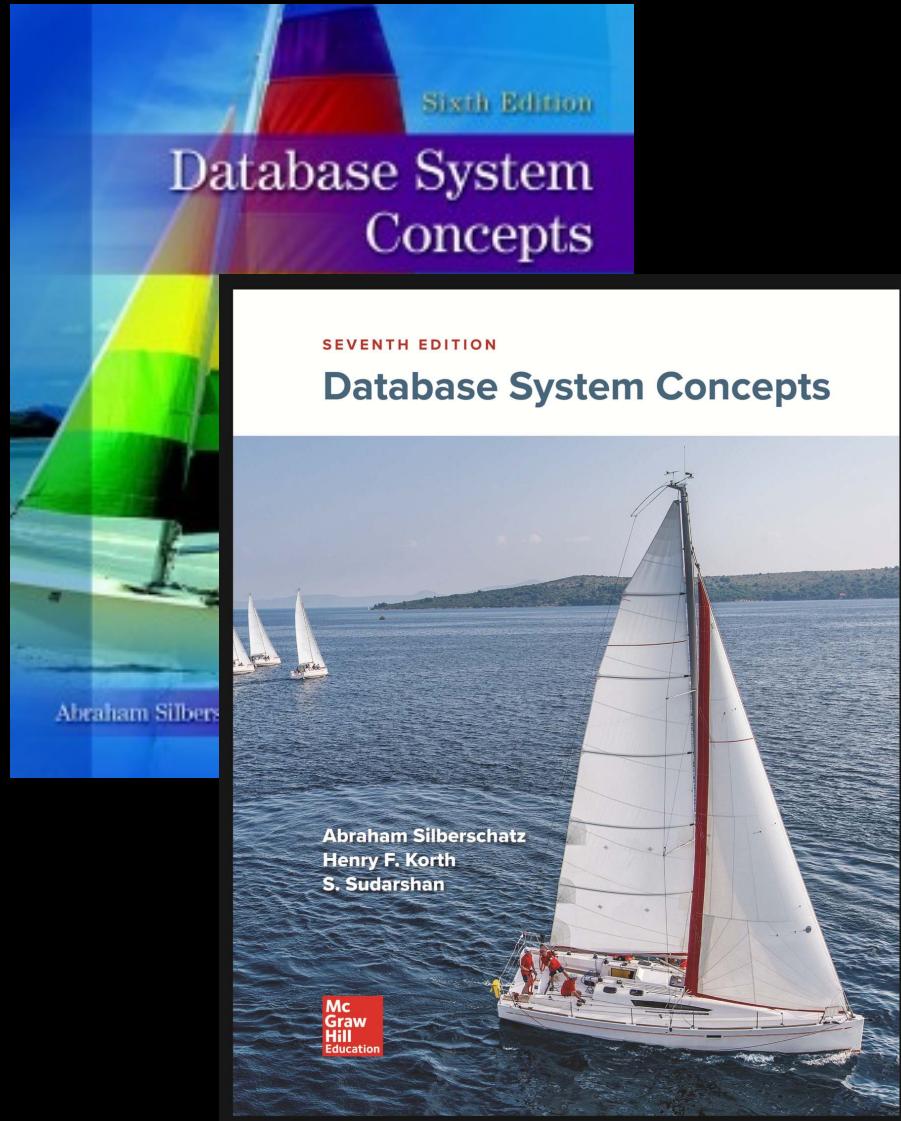

Alter

- `alter table r add A D`
 - where *A* is the name of the attribute to be added to relation *r* and *D* is the domain of *A*.
 - All existing tuples in the relation are assigned *null* as the value for the new attribute.
- `alter table r drop A`
 - where *A* is the name of an attribute of relation *r*
 - Dropping of attributes not supported by many databases.

- Chapter 6: Database Design using E-R Model

Design Phases

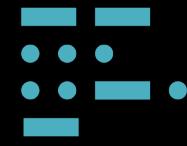

Initial phase

characterize fully the data needs of the prospective database users.

Second phase

choosing a data model

Final Phase

Moving from an abstract data model to the implementation of the database

- Logical Design - Deciding on the database schema.
- Physical Design - Deciding on the physical layout of the database

KNOWLEDGE & SOFTWARE ENGINEERING

Design Alternatives

In designing a database schema, we must ensure that we avoid two major pitfalls:

Redundancy: a bad design may result in repeat information
Redundant representation of information may lead to data inconsistency among the various copies of information

Incompleteness: a bad design may make certain aspects of the enterprise difficult or impossible to model.

KNOWLEDGE & SOFTWARE ENGINEERING

Design Approaches

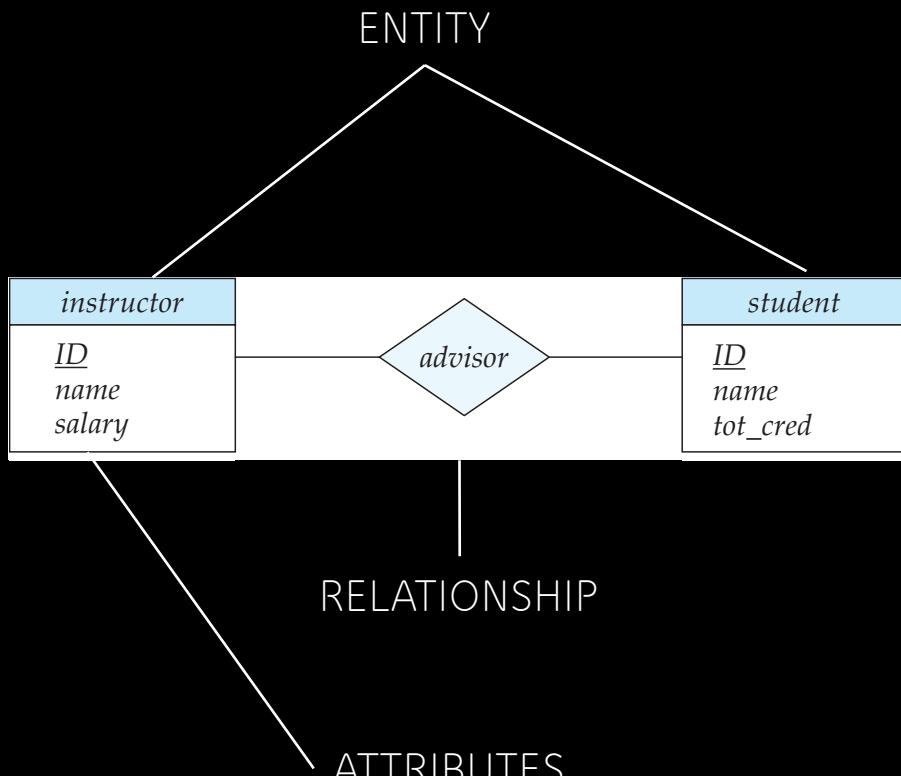

Entity Relationship
Model (covered in
this material)

- Models an enterprise as a collection of *entities* and *relationships*
 - Entity: a “thing” or “object” in the enterprise that is distinguishable from other objects (Described by a set of *attributes*)
 - Relationship: an association among several entities
 - Represented diagrammatically by an *entity-relationship diagram*:

Normalization
Theory (next
topic)

- Formalize what designs are bad, and test for them

ER model -- Database Modeling

The ER data model was developed to facilitate database design by allowing specification of an **enterprise schema** that represents the overall logical structure of a database.

The ER data model employs three basic concepts:

- entity sets,
- relationship sets,
- attributes.

The ER model also has an associated diagrammatic representation, the **ER diagram**, which can express the overall logical structure of a database graphically.

45565	Katz
10101	Srinivasan
98345	Kim
76543	Singh
22222	Einstein

instructor

98988	Tanaka
12345	Shankar
00128	Zhang
76543	Brown
76653	Aoi
23121	Chavez
44553	Peltier

student

<i>instructor</i>
<u>ID</u>
<u>name</u>
<u>salary</u>

<i>student</i>
<u>ID</u>
<u>name</u>
<u>tot_cred</u>

Entity sets can be represented graphically as follows:

- Rectangles represent entity sets.
- Attributes listed inside entity rectangle
- Underline indicates primary key attributes

Entity Sets

An **entity** is an object that exists and is distinguishable from other objects.

- Example: specific person, company, event, plant

An **entity set** is a set of entities of the same type that share the same properties.

- Example: set of all persons, companies, trees, holidays

An entity is represented by a set of attributes; i.e., descriptive properties possessed by all members of an entity set.

- Example:

instructor = (ID, name, salary)
course= (course_id, title, credits)

- *Domain* – the set of permitted values for each attribute

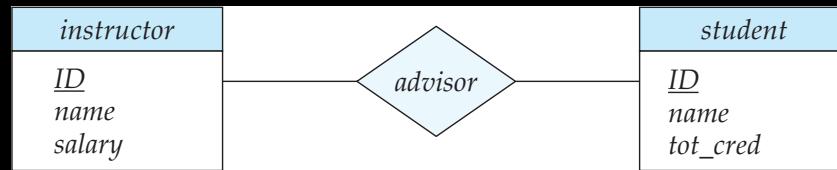

A subset of the attributes form a **primary key** of the entity set; i.e.. uniquely identifying each member of the set.

76543	Singh	76653	Aoi
22222	Einstein	23121	Chavez
instructor		student	

Example: we define the relationship set *advisor* to denote the associations between students and the instructors who act as their advisors.

Diamonds represent relationship sets.

Relationship Sets

A **relationship** is an association among several entities

Example:

44553 (Peltier)
student entity

advisor
relationship set

22222 (Einstein)
instructor entity

A **relationship set** is a mathematical relation among $n \geq 2$ entities, each taken from entity sets

$$\{(e_1, e_2, \dots, e_n) \mid e_1 \in E_1, e_2 \in E_2, \dots, e_n \in E_n\}$$

where (e_1, e_2, \dots, e_n) is a relationship

- Example:

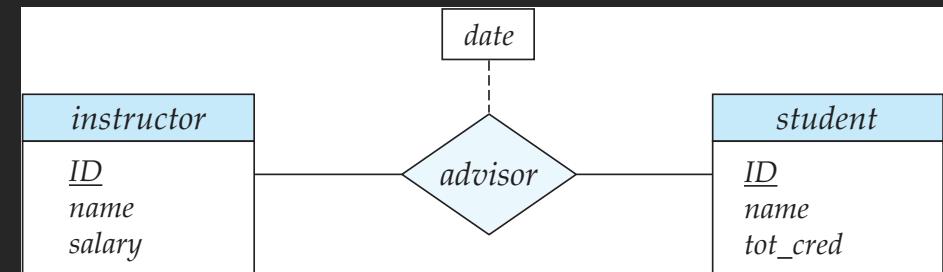

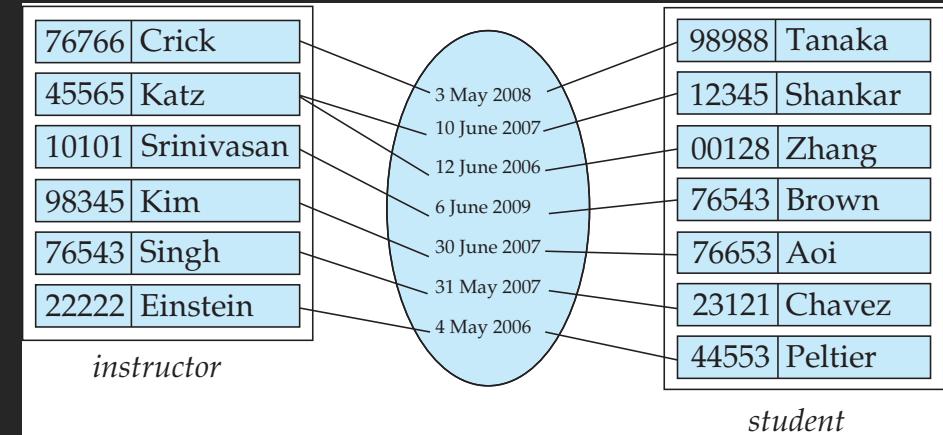

$$(44553, 22222) \in \text{advisor}$$

Relationship Sets with Attributes

An attribute can also be associated with a relationship set.

For instance, the *advisor* relationship set between entity sets *instructor* and *student* may have the attribute *date* which tracks when the student started being associated with the advisor

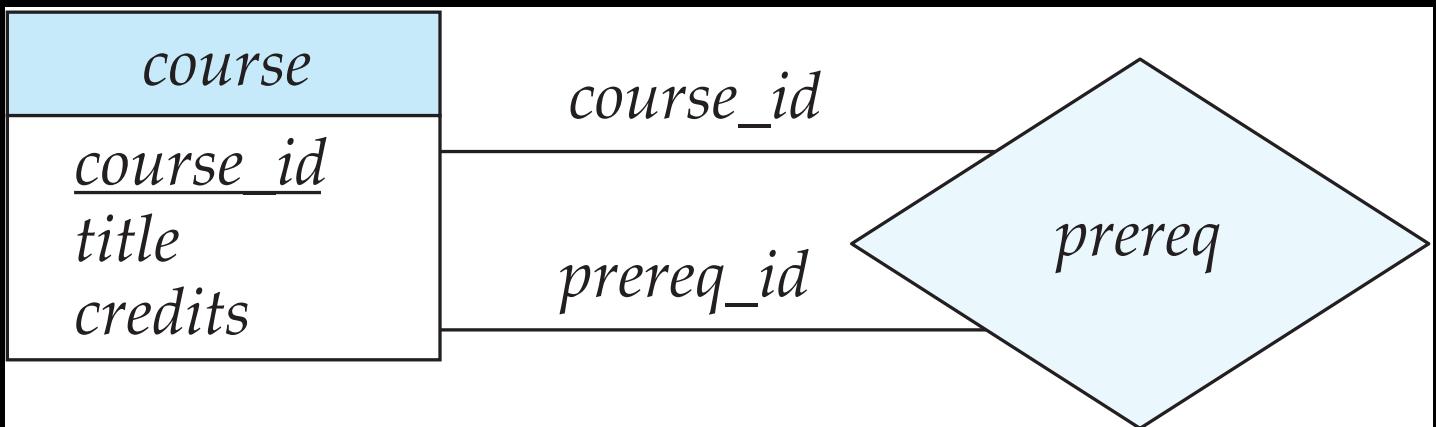

Roles

Entity sets of a relationship need not be distinct

- Each occurrence of an entity set plays a “role” in the relationship

The labels “*course_id*” and “*prereq_id*” are called **roles**.

Degree of a Relationship Set

Binary Relationship

- Involve two entity sets (or degree two). Most relationship sets in a database system are binary.

Non-Binary Relationship

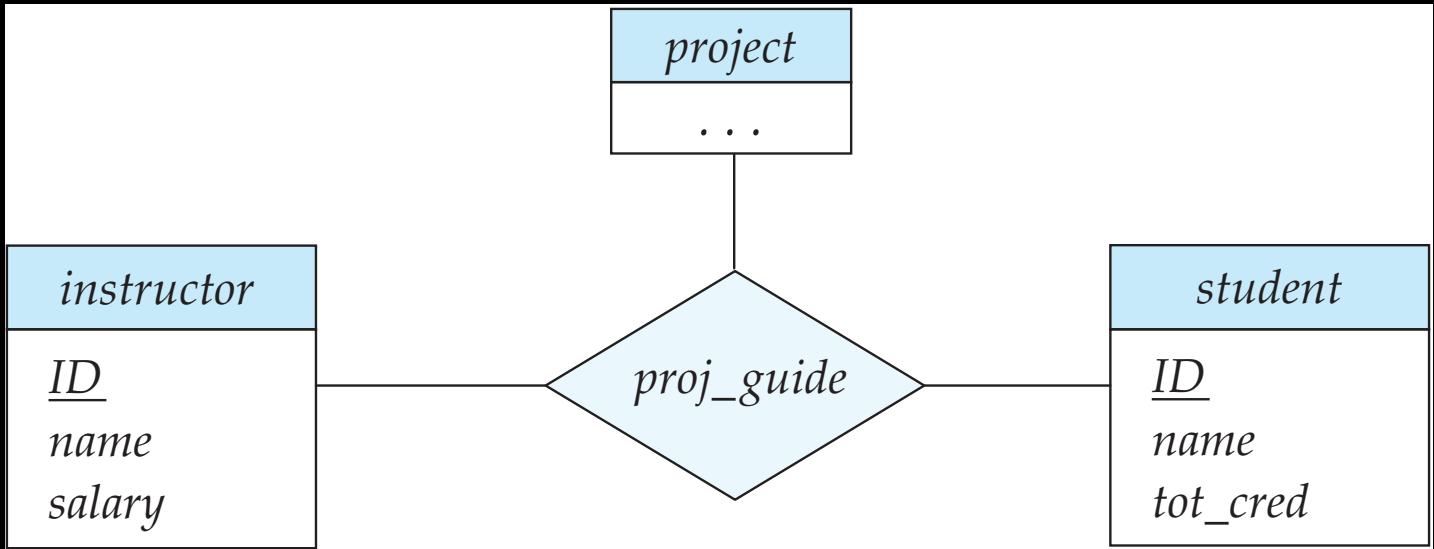

- Relationships between more than two entity sets are rare.
 - Example: *students* work on research *projects* under the guidance of an *instructor*. Relationship *proj_guide* is a ternary relationship between *instructor*, *student*, and *project*

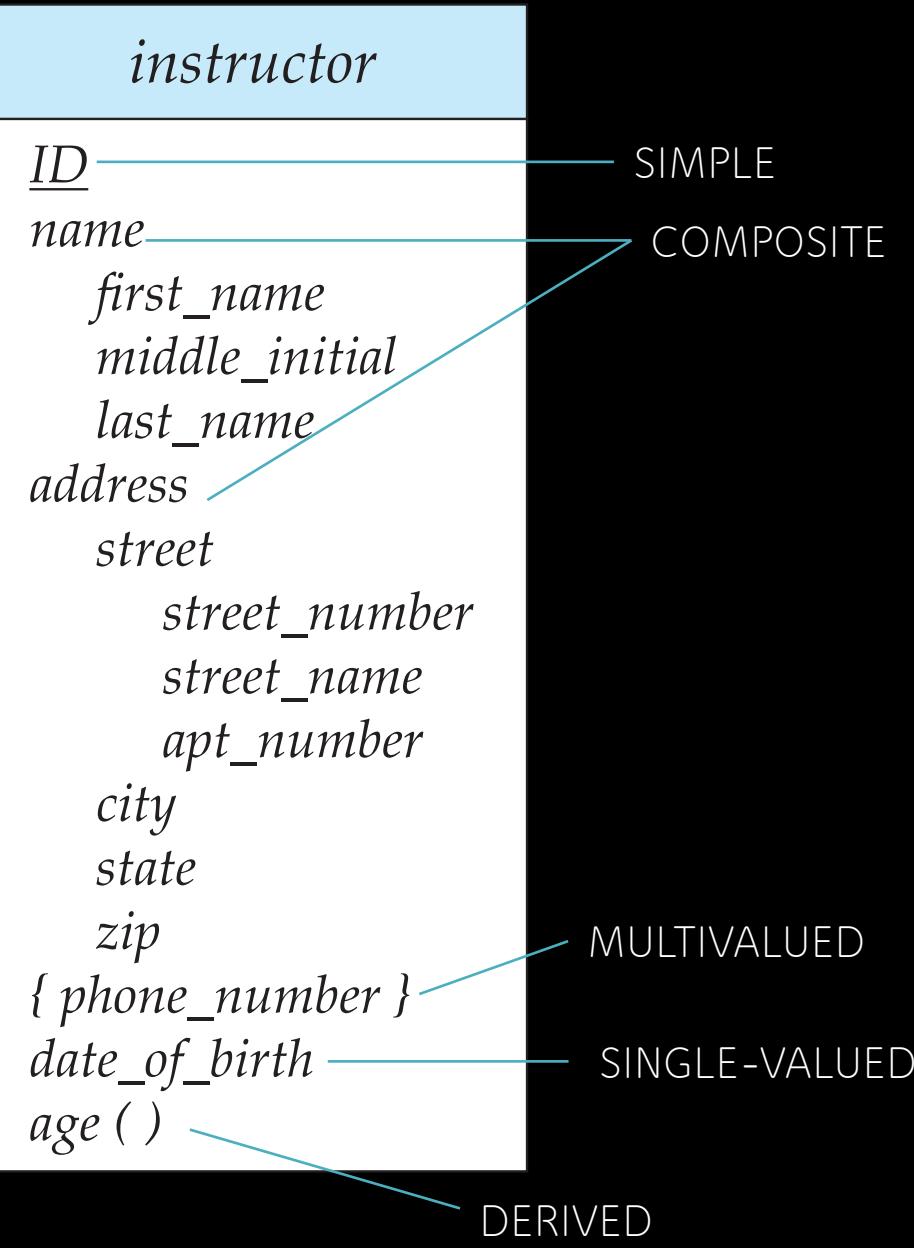

Non-binary Relationship Sets

Most relationship sets are binary

There are occasions when it is more convenient to represent relationships as non-binary.

E-R Diagram
with a Ternary Relationship

Complex Attributes

Attribute types:

- Simple and composite attributes.
- Single-valued and multivalued attributes
- Example: multivalued attribute: *phone_numbers*
- Derived attributes
 - Can be computed from other attributes
 - Example: age, given date_of_birth

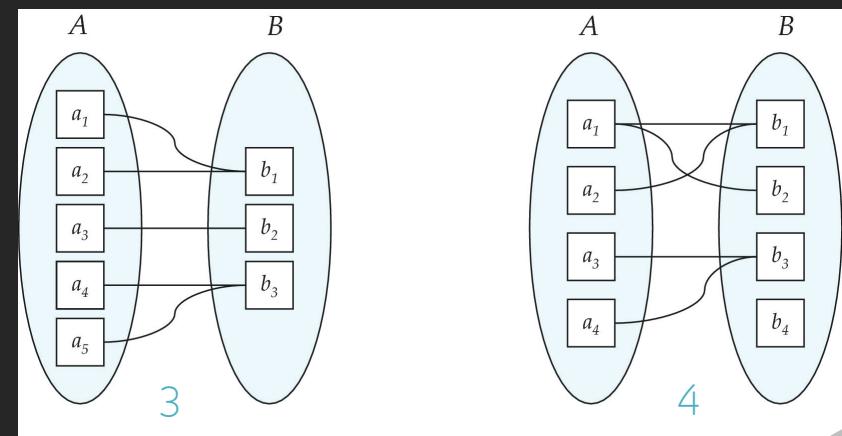

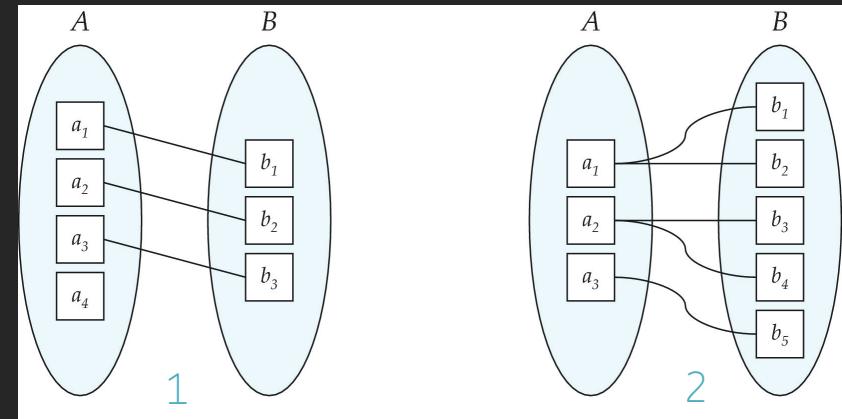

Mapping Cardinality Constraints

Express the number of entities to which another entity can be associated via a relationship set.

Most useful in describing binary relationship sets.

For a binary relationship set the mapping cardinality must be one of the following types:

1. One to one
2. One to many
3. Many to one
4. Many to many

Note: Some elements in A and B may not be mapped to any elements in the other set

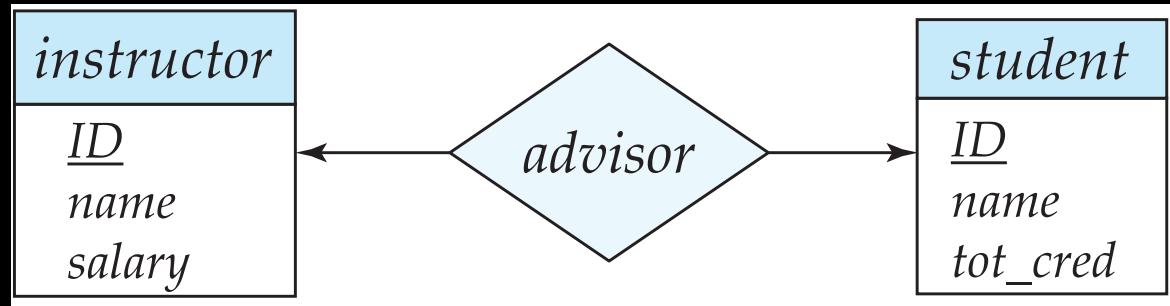

KNOWLEDGE & SOFTWARE ENGINEERING

Representing Cardinality Constraints in ER Diagram (1/2)

We express cardinality constraints by drawing either a directed line (\rightarrow), signifying “one,” or an undirected line ($-$), signifying “many,” between the relationship set and the entity set.

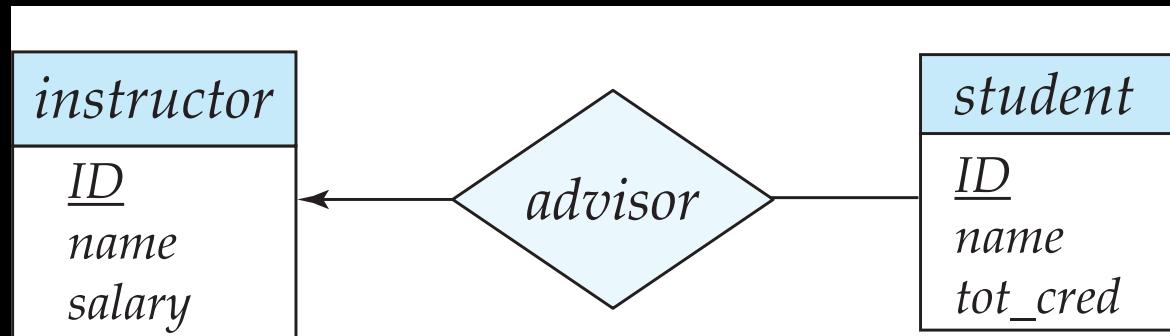

One-to-one relationship between an *instructor* and a *student*:

- A *student* is associated with at most one *instructor* via the relationship *advisor*
- A *student* is associated with at most one *department* via *stud_dept*

One-to-many relationship between an *instructor* and a *student*

- an *instructor* is associated with several (including 0) *students* via *advisor*
- a *student* is associated with at most one *instructor* via *advisor*,

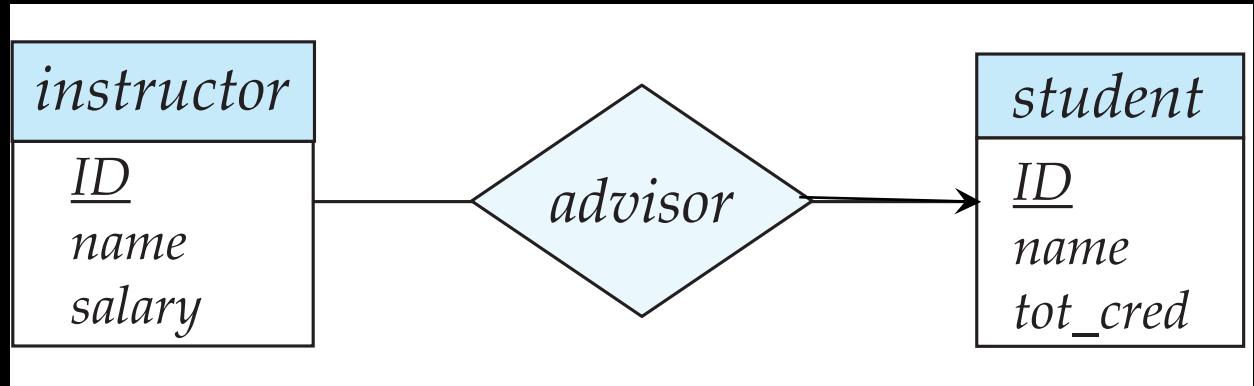

Representing Cardinality Constraints in ER Diagram (2/2)

We express cardinality constraints by drawing either a directed line (\rightarrow), signifying “one,” or an undirected line ($-$), signifying “many,” between the relationship set and the entity set.

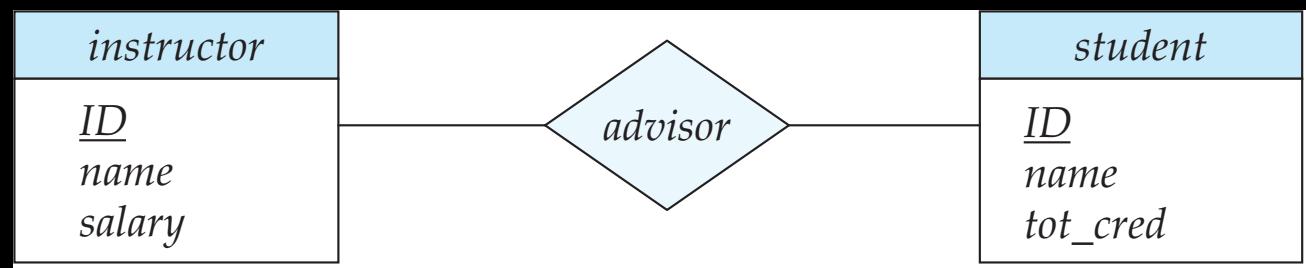

Many-to-one relationship between an instructor and a student,

- an instructor is associated with at most one student via advisor,
- and a student is associated with several (including 0) instructors via advisor

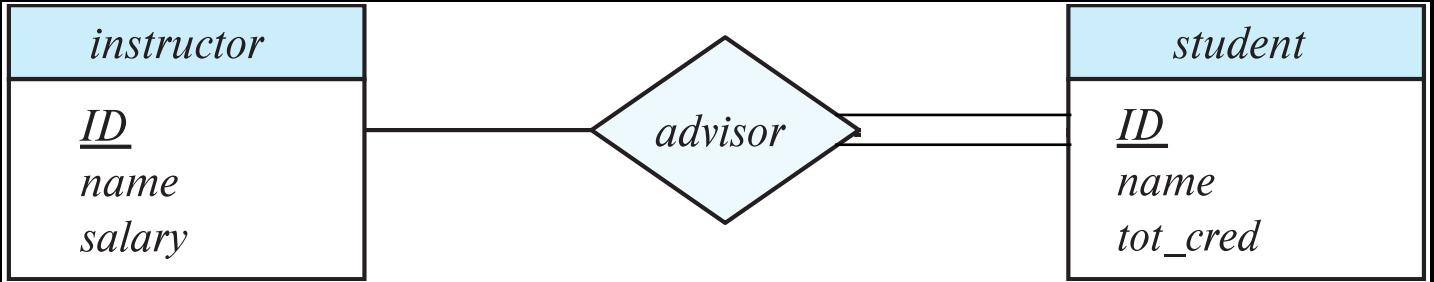

Many-to-many relationship between an instructor and a student

- An instructor is associated with several (possibly 0) students via advisor
- A student is associated with several (possibly 0) instructors via advisor ,

Total and Partial Participation

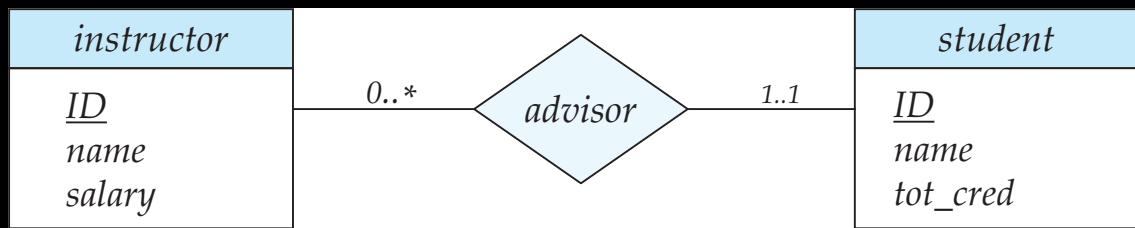

- **Total participation** (indicated by double line): every entity in the entity set participates in at least one relationship in the relationship set
- **Partial participation**: some entities may not participate in any relationship in the relationship set

- Example : participation of *student* in *advisor* relation is total
 - every *student* must have an associated *instructor*
- Example : participation of *instructor* in *advisor* relation is partial
 - some *instructor* may not have an associated *student*

Notation for Expressing More Complex Constraints

- A line may have an associated minimum and maximum cardinality, shown in the form $l..h$, where l is the minimum and h the maximum cardinality
 - A minimum value of 1 indicates total participation.
 - A maximum value of 1 indicates that the entity participates in at most one relationship
 - A maximum value of * indicates no limit.
- Example

- Instructor can advise 0 or more students. A student must have 1 advisor; cannot have multiple advisors

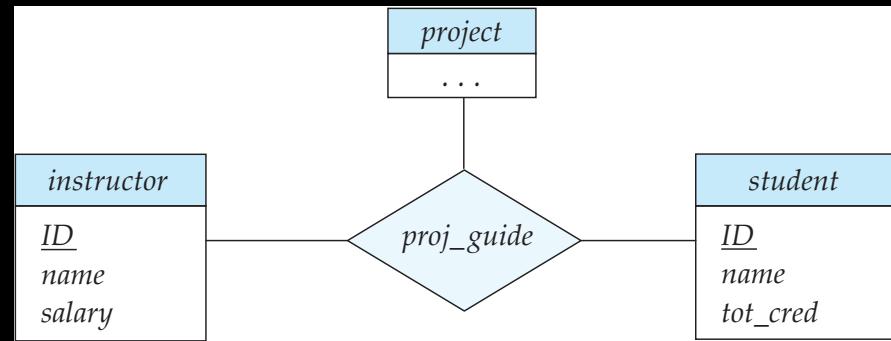

Cardinality Constraints on Ternary Relationship

We allow at most one arrow out of a ternary (or greater degree) relationship to indicate a cardinality constraint

For example, an arrow from *proj_guide* to *instructor* indicates each student has at most one guide for a project

If there is more than one arrow, there are two ways of defining the meaning.

- For example, a ternary relationship R between A , B and C with arrows to B and C could mean
 1. Each A entity is associated with a unique entity from B and C OR
 2. Each pair of entities from (A, B) is associated with a unique C entity, and each pair (A, C) is associated with a unique B
- Each alternative has been used in different formalisms
- To avoid confusion, we outlaw more than one arrow

Primary Key

Primary keys provide a way to specify how entities and relations are distinguished. We will consider:

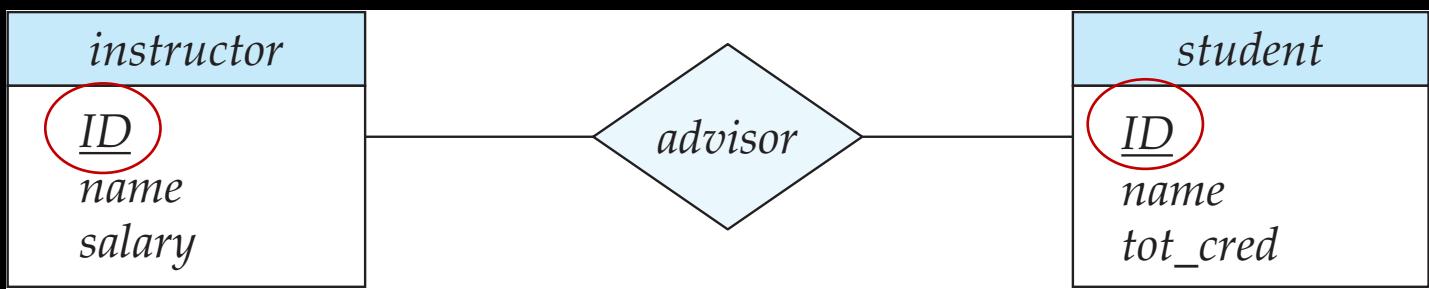

- Entity sets
- Relationship sets.
- *later on.. Weak entity sets*

By definition, individual entities are distinct.

The values of the attribute values of an entity must be such that they can uniquely identify the entity.

- No two entities in an entity set are allowed to have exactly the same value for all attributes.

A key for an entity is a set of attributes that suffice to distinguish entities from each other

Primary Key

Primary keys provide a way to specify how entities and relations are distinguished. We will consider:

- Entity sets
- Relationship sets
- later on.. Weak entity sets

To distinguish among the various relationships of a relationship set we use the individual primary keys of the entities in the relationship set.

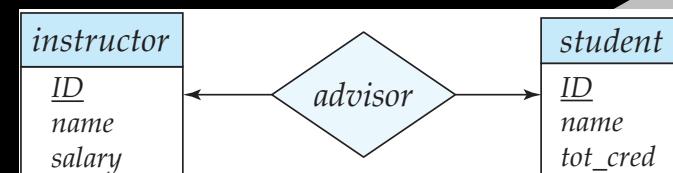

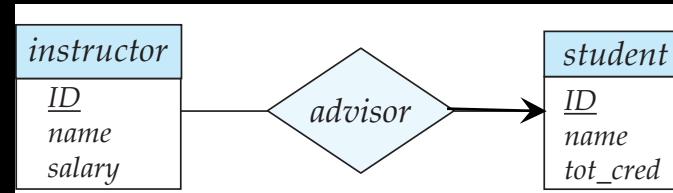

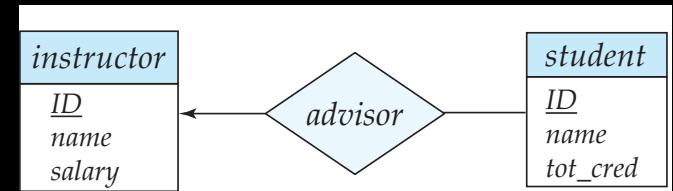

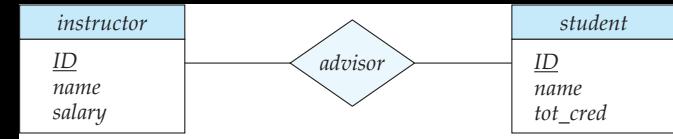

The choice of the primary key for a relationship set depends on the mapping cardinality of the relationship set.

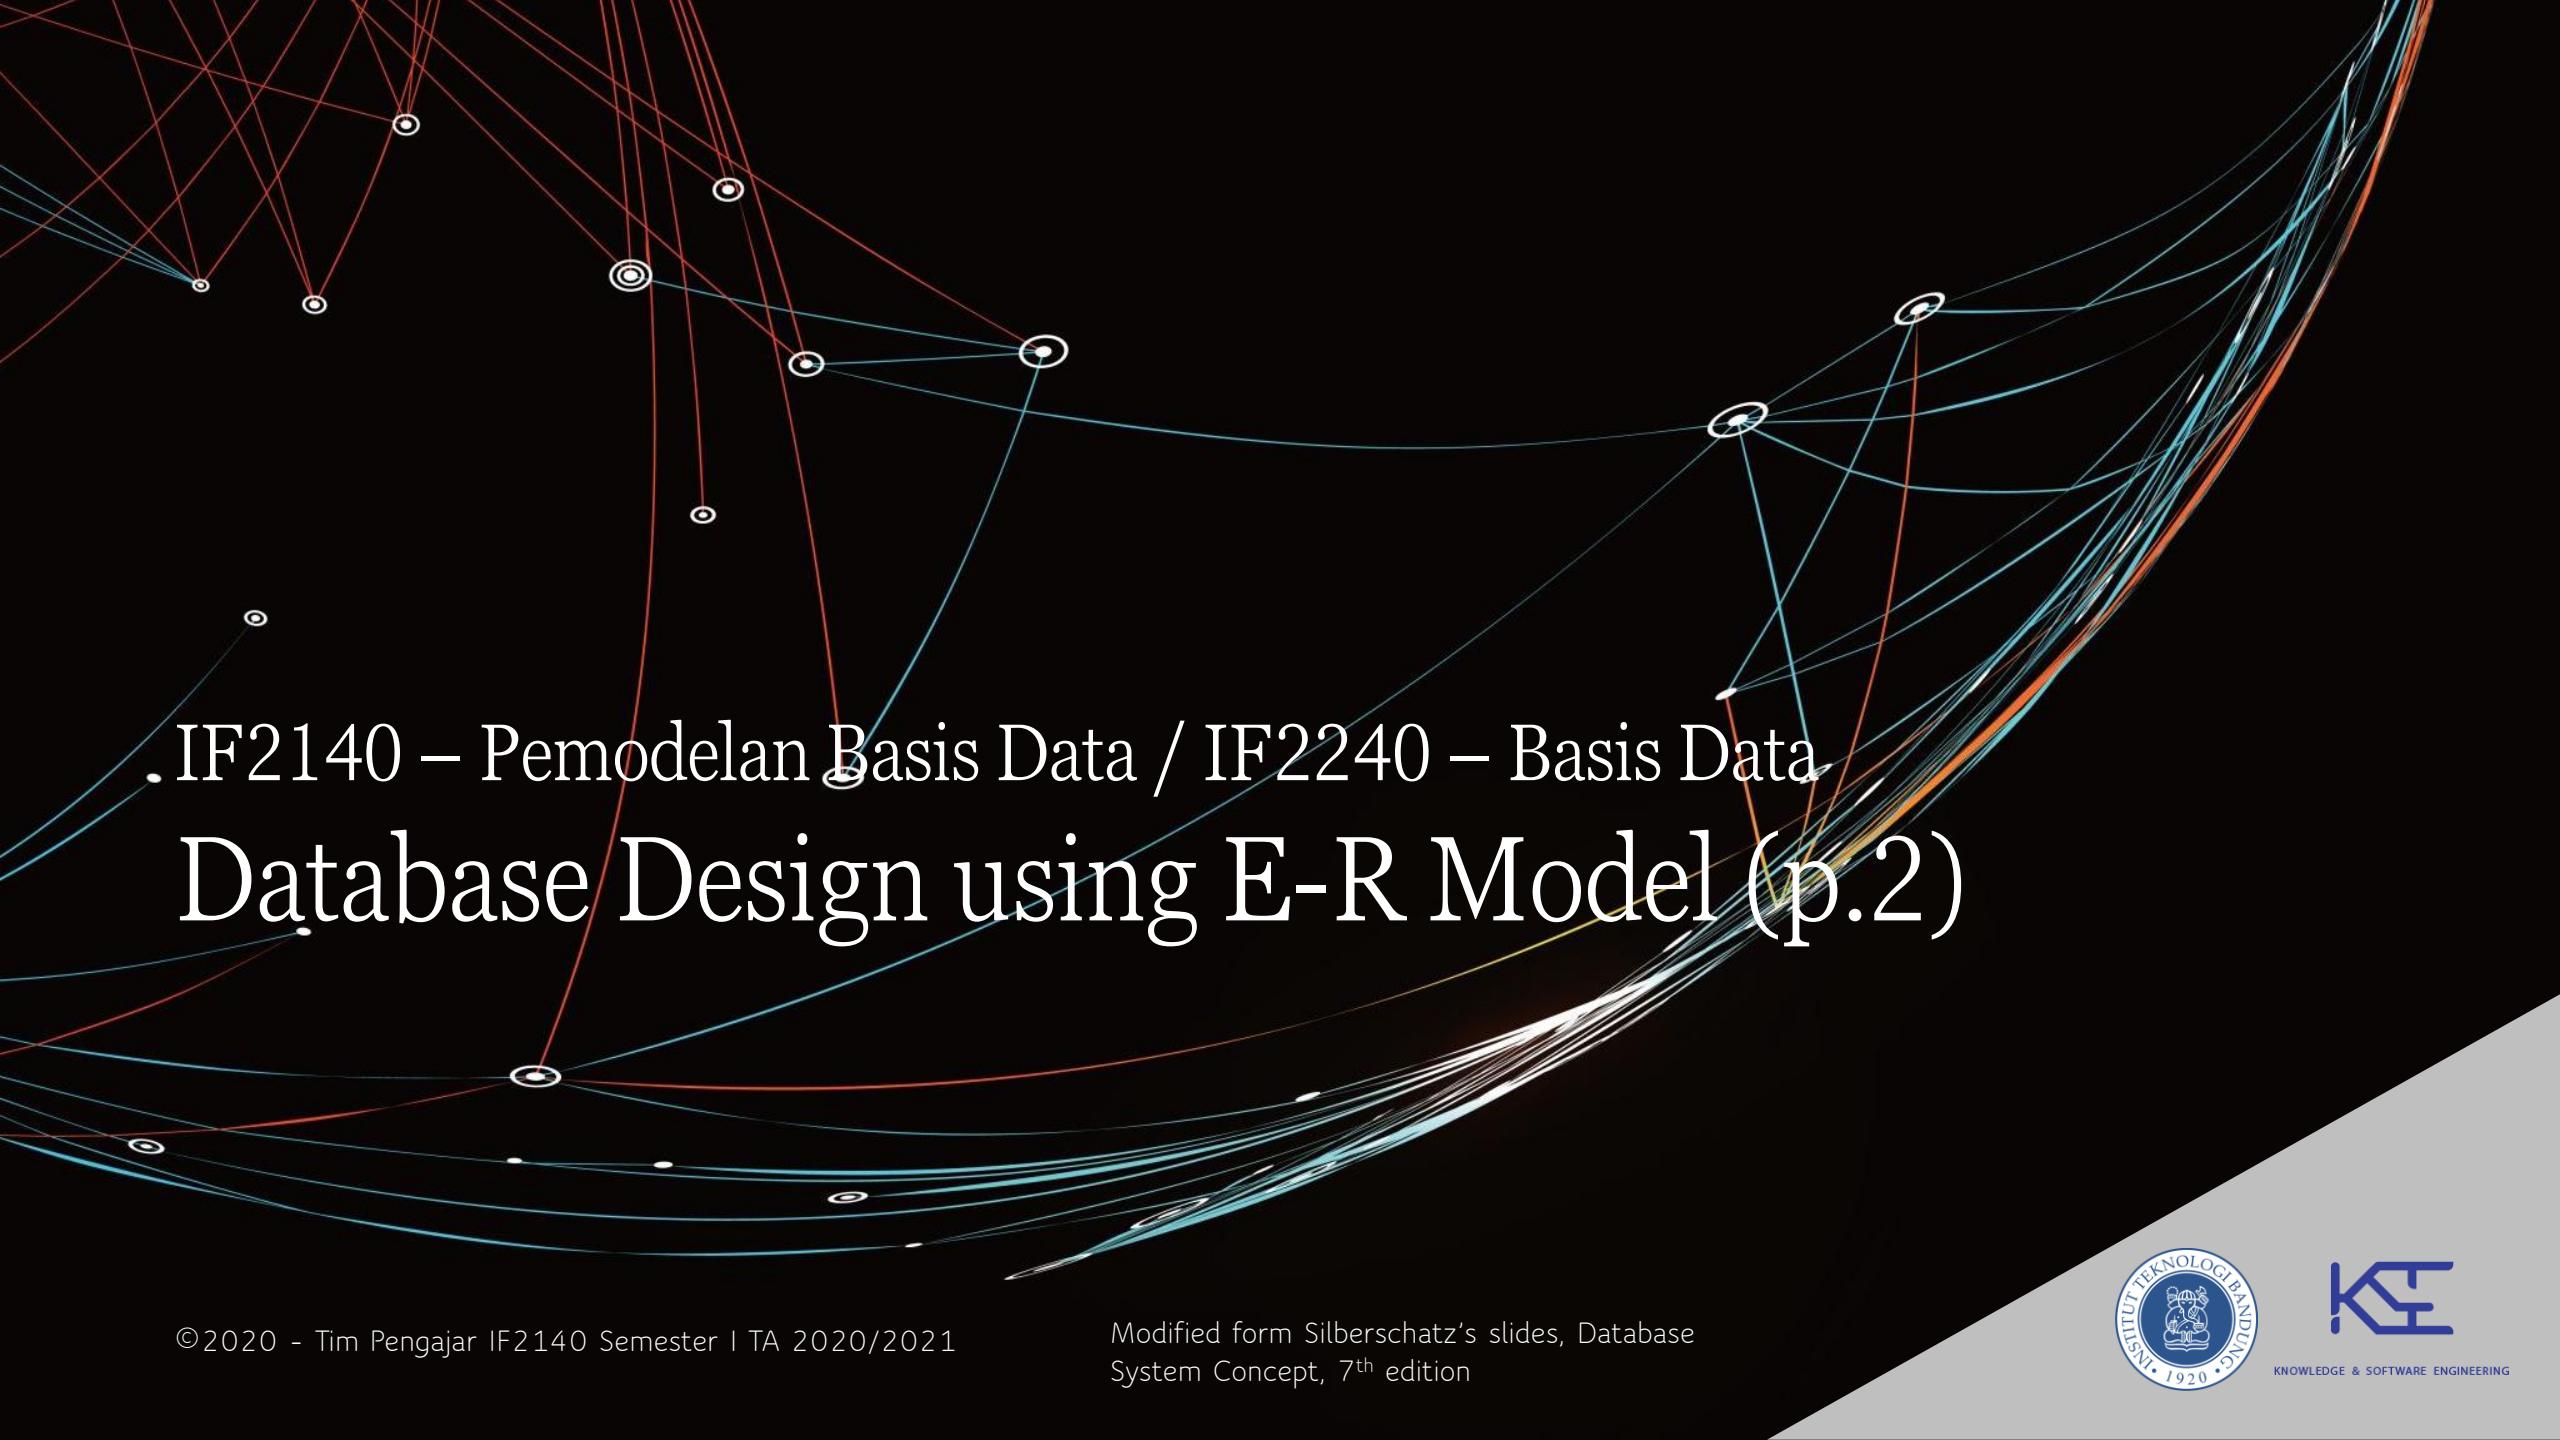

Many-to-Many relationships. The preceding union of the primary keys is a minimal superkey and is chosen as the primary key.

One-to-Many relationships. The primary key of the “Many” side is a minimal superkey and is used as the primary key.

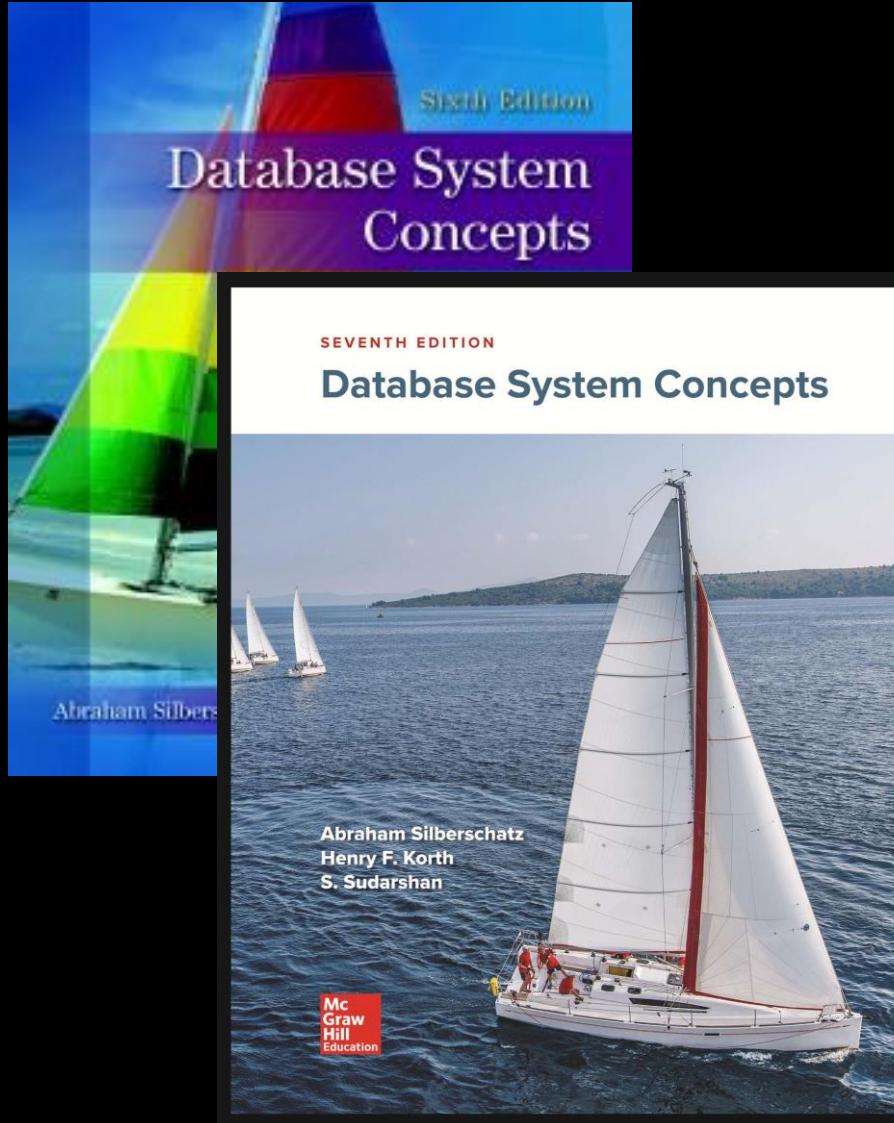

Many-to-one relationships. The primary key of the “Many” side is a minimal superkey and is used as the primary key.

One-to-one relationships. The primary key of either one of the participating entity sets forms a minimal superkey, and either one can be chosen as the primary key.

Weak Entity Sets

Consider a *section* entity, which is uniquely identified by a *course_id*, *semester*, *year*, and *sec_id*.. Clearly, section entities are related to course entities. Suppose we create a relationship set *sec_course* between entity sets *section* and *course*.. Note that the information in *sec_course* is redundant, since *section* already has an attribute *course_id*, which identifies the course with which the section is related. One option to deal with this redundancy is to get rid of the relationship *sec_course*; however, by doing so the relationship between *section* and *course* becomes implicit in an attribute, which is not desirable. An alternative way to deal with this redundancy is to not store the attribute *course_id* in the section entity and to only store the remaining attributes *section_id*, *year*, and *semester*. However, the entity set *section* then does not have enough attributes to identify a particular section entity uniquely

To deal with this problem, we treat the relationship *sec_course* as a special relationship that provides extra information, in this case, the *course_id*, required to identify *section* entities uniquely.

A weak entity set is one whose existence is dependent on another entity, called its identifying entity

Instead of associating a primary key with a weak entity, we use the identifying entity, along with extra attributes called discriminator to uniquely identify a weak entity.

Weak Entity Sets (Cont.)

An entity set that is not a weak entity set is termed a **strong entity set**.

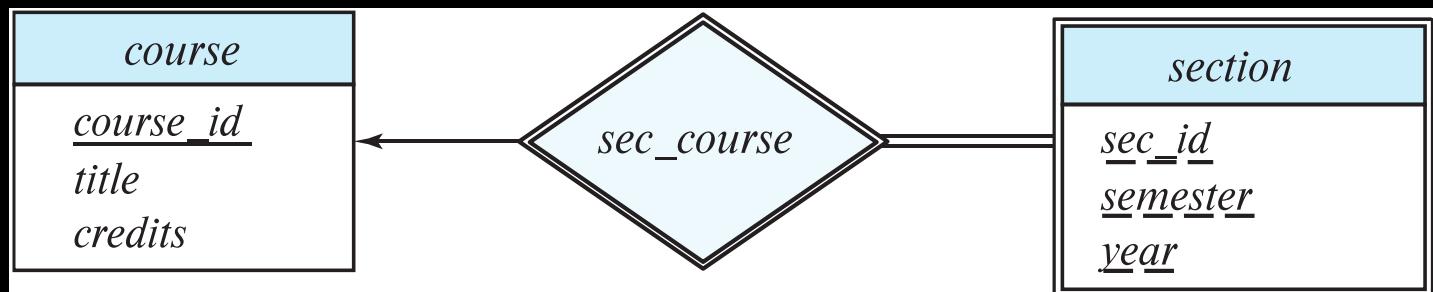

Every weak entity must be associated with an identifying entity; that is, the weak entity set is said to be **existence dependent** on the identifying entity set.

The identifying entity set is said to **own** the weak entity set that it identifies.

The relationship associating the weak entity set with the identifying entity set is called the **identifying relationship**.

In E-R diagrams, a weak entity set is depicted via a double rectangle. We underline the discriminator of a weak entity set with a dashed line. The relationship set connecting the weak entity set to the identifying strong entity set is depicted by a double diamond.

Primary key for *section* - (*course_id*, *sec_id*, *semester*, *year*)

Soal 01

Itsy Bitsy adalah perusahaan e-commerce yang menjual berbagai barang kerajinan tangan dari berbagai penjual. Saat ini mereka tengah membangun database yang akan membantu mereka dalam mencatat penjual dan masing-masing barang yang mereka jual. Masing-masing penjual memiliki nama yang unik, kontak email, alamat, dan nomor telepon. Penjual dapat menjual satu atau lebih barang, masing-masing barang memiliki id yang unik, nama, dan harga.

Pengembangan lebih lanjut, dilakukan penyimpanan informasi pembeli, berupa id, nama dan alamat (terdiri atas nama jalan, nama kota, dan kodepos). Setiap pembeli dapat melakukan pembelian. Satu kali pembelian memiliki id, tanggal pembelian, dan total harga. Untuk setiap pembelian, daftar barang yang dibeli dicatat berdasarkan suatu nomor urut tertentu yang unik untuk satu pembelian tersebut. Selain itu, untuk tiap barang yang dibeli dicatat kuantitas pembeliannya. Oleh karena itu, total harga suatu pembelian dihitung berdasarkan penjumlahan setiap harga barang dikalikan kuantitas barang.
